17. Constipation.—Goodhart gives his ideas of the mechanism of constipation, which is often credited to obstruction in the stomach and bowel. He thinks it is more likely of reflex or paralytic nature, due to the lack of peristaltic action over a certain region and that the annular stricture is less likely to bring about this condition. He is rather conservative in treatment. Bowels are made for man, not man for the bowels, and there are great individual differences in persons. He has been struck with the fact that of all those that suffer from constipation, very few give signs of retention, and he thinks the trouble is largely with the men, that they eat too much, and with women that they eat too little. As regards mucocolitis, he thinks colostomy would be a very bad practice, even in extreme cases. Clearing out the colon is not always necessary, as it has a certain digestive function of its own for food. He is rather inclined to think the condition is not really a colitis, but rather a nervous trouble in many cases. He is also skeptical as regards flatulent colic, which is often due to other causes. He also questions the theory of auto-intoxication from the intestines. We should be cautious how we charge septicity to such masters in natural asepis as are the stomach and colon.

18. Cardiac Pain.—This second lecture by Morison gives a classification of the forms of angina pectoris, classifying them

in two groups, one with pain and one without. The first type he notices in his article is the musculo-spasmodic, which he thinks may be possible, and that the quantity of blood supplied may have less to do with the trouble than the chemical changes in the muscle itself. He also notices the coronary, aneurismal, aortitic and coronary occlusive-angina as admissible types, though he does not give the exclusive importance to any of them that is credited by some. As regards aortitic aneurism he takes issue with Huchard's views. He also mentions here both intravascular and extravascular neuritic causes, the latter in the disease of the spinal cord and other portions of the nervous system as in tabes. He admits that a purely neuralgic angina is possible, and is a preferable designation to "false" or "pseudo" angina.

22. Kala-Azar.—Rogers has investigated the serum reaction of kala-azar and finds it impossible to accept the view of certain others that it is identical with Malta fever. It is in his opinion a form of malarial fever, and in this he is supported by Ross from an independent investigation in Assam.

23.—Price takes the same view.

27. Mosquitoes.—Aitken gives a brief report of his experience with mosquitoes in the North Canara District of India and notes that the anopheles can not thrive in absolutely stagnant water like the culex. He thinks possibly because it favors the infusorian parasite to which they succumb so readily. He notices that they may also be found in pools, in newly broken ground, thus favoring the old theory that breaking up ground favors malaria.

28. Mycoids.—In a former number of the *Journal of Tropical Medicine*, Dr. W. L. Braddon describes a new organism as the most frequent hematozoon to be met with in the Malay peninsula, to which he gave the term "mycoid." Clarke has gone over the subject, examined for these organisms and finds that they occur in almost every examination, including those of perfectly healthy persons, and are not affected by quinin. He thinks it is a purely physiologic phenomenon and not a parasite or a pathologic organism.

30. Transmission of Tuberculosis from Man to Cattle.—Reviewed in THE JOURNAL of November 8, p. 1219.

32. Croupous Fibrinous Rhinitis.—Moeller reviews 74 communications that have been published on this subject, including Major's as early as 1885, and other American cases. He describes the clinical picture as consisting essentially of pseudo-membranes developing in the nose without previous or consecutive diphtheria or any operative intervention on the parts. It is an acute affection, and commences with a watery discharge and increasing obstruction of the nose until it is completely closed by the membranes. Nearly every patient on record was a child. The course is generally mild, not accompanied by general symptoms, and there does not seem to be any tendency on the part of the membranes to spread beyond the nasal cavities. It may be caused by various bacteria in conjunction with some injury of the nasal membranes, but is generally the work of the diphtheria bacillus. Occasionally it has shown itself to be contagious. In one of the two personal cases described, diphtheria bacilli were cultivated from the pseudo-membranes, and in the other the pneumococcus. Treatment was restricted to removal of the pseudo-membranes and local application of boric acid.

37. Improved Writing Apparatus for the Blind.—The small portable apparatus invented by Dussaud writes the alphabet from left to right and on the side of the paper on which it is to be read, thus obviating the necessity of turning the paper over. Instead of a punch the writing is done with a small frame containing six keys, like those of a typewriter, which allow all the combinations possible of the alphabet used by the blind, and raise the letters in relief.

43. New Kind of Diphtheria Serum.—Diphtheria antitoxin acts exclusively on the toxins, but Wassermann has succeeded in producing a specific serum which dissolves diphtheria bacilli and causes both agglutination and precipitation. He suggests that it might be possible to combine this new serum with the specific antitoxin, and thus enhance the benefits of the

latter. The combination might prove peculiarly effective in convalescence from diphtheria or in cases in which the bacilli lurk in the throats of healthy persons. He mixes 20 c.c. of a 1 per cent. solution of ethylene diamine with 1 gm. of the bacilli thoroughly dried, killed and ground in a mortar. After the mixture has been shaken up together for several hours it is allowed to settle for twenty-four hours and then filtered. The toxins contained in the clear fluid that filters out are neutralized with diphtheria antitoxin, and it is then injected into animals. Rabbits have been used thus far in the experimentation.

45. Acute Syphilitic Nephritis.—A case is described in detail, observed at Ebstein's clinic, which confirms the experience of Dieulafoy, Hoffmann and others that acute nephritis may occur as one of the very earliest manifestations of syphilitic infection. The onset was severe, and in 3 cases on record it terminated fatally, but it is possible that a syphilitic nephritis may run an insidious and unrecognized course. In his case the specific infection was three weeks old, and edema, ascites and hydrothorax followed the appearance of condylomata and a painful throat affection. The urine was scanty, contained much albumin and numerous hyaline and granular casts. The patient was a robust working man, 31 years old, but the symptoms described had made him keep his bed for a week. He was rubbed daily with 5 gm. of gray ointment, and all the kidney symptoms, ascites, edema, etc., rapidly disappeared; the albumin in the urine dropped from 13.5 to 1.6 gm. in two weeks. The urine was normal when finally dismissed after seven weeks of treatment. The other manifestations of the syphilitic infection did not respond so promptly and effectively to the specific treatment as the nephritis. Karvonen has observed cases permanently cured for eight to thirteen years, but in Hoffmann's patient the nephritis recurred later.

47. Typhoid Bacilli in Sputa.—In the case first described the patient had succumbed to a fibrinous pneumonia associated with typhoid fever. Pneumococci were found numerous in the lung at the autopsy, and with them a few typhoid bacilli. The latter had probably been occasionally present in the sputa during life. In a second case a young man in the fourth week of a severe typhoid fever, as convalescence was approaching, suddenly exhibited severe symptoms on the part of the lungs, dyspnea, cyanosis and pulse rising from 80 to 120, with pain in the right side and marked increase in temperature. The sputum was foamy and streaked with blood. The heart action was so weak that stimulants were necessary. These symptoms gradually subsided in the course of six days, and the area of dullness which had developed suddenly, also vanished, and the sputa were no longer blood streaked. A serous effusion developed in the right pleura, but was gradually absorbed and convalescence progressed undisturbed. The sputa contained large numbers of typhoid bacilli for fourteen days, and a few pneumococci. Only a few cases have been published in which these bacilli were isolated from the sputa, and none in which a primary pneumo-typhoid developed in consequence of inhalation of bacilli in the dust of such sputa. It is very probable, however, that such dust alighting on articles of food may be the cause of abdominal typhoid. The sputa of Dieudonné's patient contained numerous typhoid bacilli for seven weeks, long after he had apparently recovered. The hemorrhagic character of the sputa was mentioned in every similar case on record. This hemorrhagic character may be due to an infarct in the lungs as well as to a pneumonia. In this case typhoid bacilli in the blood might get into the alveoles and be coughed up in the sputa. In a third case described a bacteriologist who had been working with extremely virulent typhoid cultures developed typhoid fever. In the third week he complained of pains in the lungs and an area of dullness developed on both sides with increasing fever. The sputa were viscous bright red balls; no typhoid bacilli could be found in them. An exploratory puncture on the thirtieth day revealed a serous, slightly hemorrhagic effusion in the pleura, which contained typhoid bacilli in large quantities. About 50 c.c. of the purulent effusion was removed the fifty-second day, after which the temperature dropped to normal. There had been no exper

toration for some time, when the sixty-fourth day the patient coughed up a quantity of slightly hemorrhagic sputa. Exploratory puncture the eighty-fourth day failed to disclose further effusion, and the area of dulness observed was ascribed to a fibrinous pleuritis, but two days later, after dismissal, violent coughing occurred as the patient was ascending the stairs, and he coughed up about 200 c.c. of pus. Pure cultures of virulent typhoid bacilli were derived from the pus of the pleural empyema in this case. In a fourth the autopsy disclosed a hemorrhagic infarct in the lungs from which pure cultures of the pyocyaneus were derived. Death had occurred the twenty-sixth day of a severe typhoid fever, exhibiting the last two days hemorrhagic sputa with dulness and crepitus in the lungs. Mixed infection in the course of typhoid fever is a more serious condition than a pneumonia caused by the typhoid bacillus alone, as a second infection is superposed. It is still a question whether the typhoid bacillus alone is able to induce a lobular pneumonia, although Jehle has reported five cases in which he succeeded in isolating the typhoid bacilli, once in a pure culture, and once after influenza, associated with diplococci and staphylococci.

48. Suggestions for Early Diagnosis of Cancer.—Boas urges the general distribution of circulars warning against cancer, similar to the one recently issued by the Belgian government in its prophylaxis against venereal diseases. He thinks that if the public generally were instructed in the early symptoms of cancer, persons affected would apply to a physician at the first indications, instead of wasting time on treatment of supposed stomach troubles, hemorrhoids, etc. He states that of the 54 cases of cancer of the rectum in his experience since 1896, 80 per cent. were already inoperable when first seen. The carcinoma had not been diagnosed in the overwhelming majority, although in many instances there had been digital exploration of the region. He further urges that in all cases suspicious of cancer the patient should be admitted to a hospital and kept under observation for one to three weeks, returning for a second investigation if the result of the first had been dubious. Besides the benefit to the public from such measures, students and physicians would acquire valuable training in the early recognition of cancer.

53. Statistics of Tertiary Syphilis.—Weber's article is the result of five years' study of syphilis at Jadassohn's clinic at Berne, and supplements the latter's communication in regard to tertiary syphilis among the prostitutes of Breslau. The figures show that tertiary manifestations occasionally develop even after several courses of thorough mercurial treatment. Weber tabulates the statistics of 185 cases of tertiary syphilis in the clinic, and of 49 in private practice. No treatment had been applied in 77.3 per cent. of the former nor in 40.8 per cent. of the latter. Applying the principle followed in the Breslau statistics he collated all the cases of syphilis at any stage and found that 51, or 34.7 per cent., of 147 private patients who had been insufficiently treated or not at all, presented tertiary symptoms, while only 13, or 5 per cent., exhibited them out of 261 who had taken more than one course of treatment. There was thus a difference of 29.7 per cent. between the two groups. This difference amounted to 54.6 in those who had been under observation for more than one year, and to 58.5 per cent. in those under observation for two years and more. He groups his material in various ways, and the result is always in favor of thorough treatment as materially reducing the tendency to tertiary manifestations later. The cases of recurrence of tertiary accidents also showed that a third of the patients had not been treated for their primary affection. Also that those treated with iodid alone were in the majority.

56. Symptomatic Treatment of Tuberculosis.—In this review of his experiences as director of the great sanatorium at Alland, Weismayr mentions that he has frequently conquered the night sweats by ordering a harder bed, lighter night clothes and keeping the room cool, with open windows. A cold sponge may prove effective, especially when vinegar is used. Brehmer used to recommend as a sovereign remedy a glass of milk with two teaspoonfuls of brandy on retiring. Formalin and tannin are the most effective external measures. The patient is

swabbed with a mixture of equal parts of 40 per cent. formalin and alcohol, the first evening on the back and arms, the second on the legs, the third on the front of the trunk. The result is prompt, enduring and free from by-effects. Dohrn applies the formalin in a soap which is allowed to dry on. Weismayr has found the salvia preparations useful in cases of night sweats, giving 20 drops of the tincture in the morning and 30 at night. Lead acetate is still more effective. He prescribes it in the formula: .03 gm. plumb. acetic.; morphin. hydrochlor.. .005 gm., and sacchar., .3 gm., in two doses during the evening. In case of vomiting he has the patient eat oftener and smaller amounts and recline afterward, taking iced soda water. He has also seen good results follow the administration of 5 to 10 drops of tincture of iodine with .1 gm. of potassium iodid in water during the day, to correct digestive disturbances. A tendency to constipation will frequently yield to a glass of cold water before breakfast, supplemented by stewed fruits, sour milk or one-day kefir. The fever will generally subside on enforced repose, but if not, it is important to reduce it at meal times by medicinal means. Also in the cases that are free from temperature in bed but acquire it as soon as the patient gets up. He prefers pyramidon for the purpose: .25 gm. dissolved in half a glass of water, and slowly sipped in the course of a half hour before the anticipated rise in temperature. The fever is checked by this measure in every case, almost without exception, and sweating rarely follows, while no untoward effects were observed. Kobert attributes to pyramidon a stimulating action on the heart. He warns against allowing patients to become hypochondriac on the subject of temperature measurements. It is better to abandon the thermometer.

57. Pyoktanin in Eye Affections and Chancroids.—It is twelve years since Stilling proclaimed the merits of pyoktanin as a powerful antiseptic, free from toxic and caustic properties, while, contrary to other antiseptics, it does not coagulate albumin. Physicians have been slow to take advantage of it, but in veterinary circles it is being used more and more extensively every year. It is indispensable that the pyoktanin should come into intimate contact with the tissues, and consequently it must be applied in the form of a powder or very strong solution. A weak solution is absorbed by the dressing, and the tissues do not feel its effects. Weill has been using it for ten years in eye affections, and states that the cornea and conjunctiva bear well a 1/100 solution or powder. He has also found it more effective than any other remedy for the treatment of chancreoid when it can not be excised. He applies it pure in the form of a powder after curetting, and repeats daily or at brief intervals, removing the scabs that form until they are not easily detachable. When the firm scab at last drops off, the surface beneath is covered with healthy granulations, which do not stain blue with the pyoktanin. Four or five months may be necessary to complete the cure. The blue discoloration is the only drawback to this remedy.

59. Treatment of Affections of Testicles and Adnexa on New Principles.—Zabludowski has charge of the Berlin University Massage Institute and has found that many cases of inflammation and disturbances in the testicles and their adnexa can be cured by scientific stimulation of the nerves and circulation in the parts. His method of treatment includes massage manipulations, kneading and intermittent compression of the parts to diffuse and hasten the absorption of infiltrates and exudates; milking movements and stretching to cure thickening and shortening of the seminal cord, and twisting to detach adherences, but the principal factor in treatment is to induce rapid and violent changes in the circulation by means of repeated constriction with an elastic rubber band or tube 8 mm. wide and about 160 cm. long, which is wound around the roots of the penis and scrotum and left for fifteen to twenty minutes. By this time the venous congestion is intense, and when the compression is removed the arterial blood streams copiously through the parts. He describes the technic of the various manipulations, which must be graduated not to cause pain nor excitement. The indications for this very effective treatment are protracted inflammation of the testicles, epididymis and seminal cord of traumatic or gonorrheal origin, after the acute

stage has passed. Also functional disturbances with or without slight anatomic alterations; acquired or slight congenital shortness of the cord; atrophy *ex inactivitate*; sensory or motor disturbances and pathologic secretion. The sittings are repeated daily for ten to twenty minutes and continued two to eight weeks. The most rebellious cases are usually those that have been treated with cold applications at some previous stage. His experience has been extensive, and he advocated this method of treatment, with details of cases at the recent Naturforscher Congress.

61. Changes in Visual Field in Syphilis.—Ziemssen calls attention to the fact that a syphilitic affection of the brain or spinal cord is often associated with an affection of the optic nerve, limiting the field for red and green, even when the general visual field is unimpaired. The course of the main affection can be traced by inspection of the visual field as the conditions improve or grow worse, and it is thus a criterion of the benefits from treatment. In some of his patients the improvement was marked under mercury, but as soon as it was suspended the visual field gave evidence of retrogression. The more intense the treatment and the longer it was continued, the better the results in the visual field.

63. Sahli's Test of Stomach Functions.—Sahli's "flour soup" test was described in THE JOURNAL of May 31, 1902. Bönninger has been giving it a thorough trial and says that research in this line will aid in solving certain hitherto obscure problems, but that in the clinic, as a general rule, the older methods still hold their own in comparison.

64. Excision of Nomatous Gangrene.—Ranke illustrates a case of extensive noma of the genitalia and buttocks which developed during measles in a girl 3 years old. He treated it by prompt excision of all the diseased portions, as in three previous similar cases. All the patients made a smooth recovery. During the fifty-eight days spent in the hospital the child increased 22 per cent. in weight, a daily gain of 57 gm., about 2 ounces. In the other cases he supplemented excision with thermocauterization.

65. Ovariectomy During Pregnancy.—Graefe adds 27 cases, including 3 in his own experience, to the 148 on record of ovariectomy undertaken during pregnancy. The mortality of the mothers in the entire list was 2.3 per cent. One of the deaths occurred three months after the intervention, which could scarcely be incriminated in this case, and one death was inevitable, as extensive gangrene was found on operating. The last 126 operations contain only this one fatality. In 119 cases the pregnancy was interrupted by the intervention in only 19, or 16 per cent. In the last series of 27, abortion followed in 5 and premature delivery in 3. This series includes the American cases of Jarman and Kahn. The pregnancy continued undisturbed in two cases with numerous adhesions or torsion of the pedicle of the tumor. In the cases in which abortion occurred there must have been some predisposition to it, possibly from decidual endometritis as the trauma of the intervention was slight. Abortion would probably have occurred even without the operation. The statistics show that ovarian tumors, during a pregnancy, induce abortion in 17 per cent. if left unoperated. After ovariectomy the pregnancy was interrupted in only 22.5 per cent., and a third of this number presented urgent indications for surgical relief. The results of expectant treatment have been a maternal mortality of 39.2 per cent. and a fetal of 67 per cent., according to Orgler's and Winckel's statistics. Six of the cases in the series demonstrate that even after evidences of impending abortion have appeared, prompt ovariectomy will afford relief, and the pregnancy will continue its course uninterfered with.

66. Suture of Bladder After the High Operation.—Hofmann recommends his practice of keeping the patient in bed and curing the cystitis before attempting to operate for the removal of a foreign body in the bladder. The time thus spent shortens the after-treatment, as the inflammation once cured, the incision in the bladder can be made without fear, and it is sure to heal smoothly after immediate suture.

68. Review of 720 Gallstone Operations.—Kehr's total mortality has been 15.5 per cent., and excluding the compli-

cated cases requiring additional interventions on stomach or liver, carcinoma, etc., the mortality during the first hundred days after the operation was 3.5 per cent. He has been able to save a number of cases of diffuse cholangitis with putrid pus in the bile duct and liver. The patients would inevitably have succumbed without intervention, and if it is possible to save thus 3 per cent. of these apparently inoperable cases, it is the surgeon's duty to act. He can not be sure of the diagnosis before operating. Kehr has had only one case of peritoneal sepsis in his last 300 gallstone laparotomies. He finds that elderly persons bear the operation surprisingly well. His experience has also shown that a chronic interstitial pancreatitis is liable to cause the same clinical picture, cachexia, icterus, etc., as a carcinoma in the pancreas. An operation, however, may save the patient in the former case. He is impressed more and more with the advantages of draining the hepatic duct. He has done it 49 times in cystectomies, 6 times with cystostomy, 29 times with cystectomy and cysticotomy, and 6 times alone. He has been draining the hepaticus for six years, and has found that the loss of bile had no serious effect on the digestion, although in some cases all the bile was thus drained away for two weeks, a loss of 500 to 800 gm. of bile a day. The only symptoms resulting were the moderately lessened appetite and somewhat difficult defecation. He inserts a tube the size of the little finger, after the bile duct has been opened above the duodenum and all the accessible stones removed. The tube is introduced for a distance of 4 cm. Unless certain that the bile duct is completely free from stones, he inserts a second tube in this duct also. This favors later irrigation of the duct and removal of stones overlooked at first. He advocates this drainage of the hepatic duct after ectomy as the rational method of treating chronic recurring cholelithiasis. The mortality is less than after choledochotomy with suture as the operation is more rapidly concluded, and infection in the hepatic duct can be more easily cured. The surgeon is far less liable to overlook stones, as they are frequently discovered in the after-treatment. In one case a stone was thus found too large to be extracted. A laminaria was inserted liverward through the incision in the bile duct, and the hepatic dilated by this means until the stone could be easily extracted twelve hours later. The swelling of the laminaria was extremely painful to the patient, but it accomplished its purpose. He has never witnessed any untoward effects from this hepatic drainage. The flow of bile usually ceases by the third week and the wound heals by the sixth. He has never observed a case of actual recurrence of stones after they have been completely evacuated, but thinks it is possible with a fresh infection of the biliary passages.

69. Clinical Importance of Indicanuria.—The results of examination of 40 patients with gastrointestinal affections and a large number of others with leukemia or anemia, Addison's disease, Bright's disease or affections of the liver or spleen are tabulated for comparison. They demonstrate beyond question that besides the indican derived from excessive intestinal putrefaction, there is another source for the indican in the urine, namely, in altered metabolism. Indicanuria is a constant symptom that aids in the diagnosis of insufficiency of the liver. It is also an important symptom in splenopathy of infectious origin.

70. Hematology of Chloroform Narcosis.—Solimei concludes from his extensive research that it is possible to determine the prognosis of a chloroform narcosis by examination of the blood, and also whether all the anesthetic has been eliminated from the system. The influence of the chloroform lasts from a few hours to several days in different individuals, and the changes it induces in the blood are in direct proportion to the amount of the anesthetic used. They are not all due to the chloroform but form a vicious circle. In tests on animals the blood had a strong odor of chloroform and coagulation occurred unusually slowly. The number of red corpuscles diminished, the decrease manifest even as late as forty-eight hours, while the proportion of whites increased. The spectrum of the arterial blood was characteristic of methemoglobin if the narcosis had been deep or protracted. The blood cells also

became altered in shape to a certain extent. The proportion of oxygen in the blood diminished while that of carbon dioxide increased. The deleterious action of chloroform is more marked on the venous than on the arterial blood.

71. Treatment of Lupus with Formalin.—Matteucci first curettes and removes all suspicious tissue, under cocaine or chloroform, and six days later applies a compress impregnated with a 10 per cent. glycerin solution of 40 per cent. formaldehyde, preceded by a little cocaine. The compress is left in place twenty-four hours and then renewed day after day. In two weeks a pink zone of healthy tissue replaces the lupus patches. Three years' experience has convinced him of the great advantages of this method of treating lupus. It is especially useful when the mucosa is involved, and it may be supplemented by Thiersch or Lang flaps. Dusting powders should be avoided, as they interfere with the action of the formalin. He has also applied it in a few cases of epithelioma with good results.

73. Scoliosis of Sciatica.—Cappuccio has observed Vanzetti's sign of scoliosis in six patients, and notes that the pelvis in sciatica is invariably held horizontal, while in other lesions of this region it is more or less inclined. This horizontal attitude of the pelvis in spite of the marked scoliosis is a valuable differentiating sign for sciatica. It is easy to understand the mechanism of the scoliosis, as the effort is to spare the inflamed nerve trunk, while in hip-joint disease the attitude is the result of the effort to spare the joint. His cases are illustrated.

75. Medicated Steam for Affections of Upper Air-Passages.—Della Vedova has been using for some time in the treatment of catarrhal affections of the upper air-passages an apparatus which sprays them with a medicated steam. The heat, the steam under pressure and the medicinal substance combine to affect the mucosa favorably, and his experience has been remarkably encouraging in regard to the value of this "rhinovaporization," as he calls it. He has found that certain mineral waters were peculiarly adapted for spraying in steam by this means, Salsomaggiore and Salice waters in particular.

79. Trendelenburg's Method of Treating Varices.—Ronchi has collected 655 cases of varices treated by 26 various surgeons with the Trendelenburg method of ligating the saphena. He adds that 29 out of 69 cases in his own experience were operated on, and by this method. The results demonstrate, he thinks, that this method of treatment, alone or combined with excision of the largest varices, is to be preferred to all other methods of intervention.

80. Steam Treatment of Carbuncle.—Gucciardello gives a cut of a little instrument he had invented for the purpose of applying a medicated spray to a carbuncle or similar lesion. The steam is generated in a small vessel, and emerges through four parallel and tapering tubes, which issue horizontally from the top of the vessel. The tips of the tubes form a square that includes the center of the lesion. He uses a 2 per cent. solution of carbolic acid for generating the steam. It is applied three or four or even more times a day, for a half to one hour each time, just avoiding scorching the tissues. Between the applications a compress wet with a solution of sublimate is applied. In four to nine days at farthest the necrotic portions are eliminated and the lesion heals from beneath with no loss of substance from the knife or cautery. He describes 7 cases thus treated with the best results. The application is not painful and recovery is prompt.

87. Lecithin in Therapeutics.—Seroni regards the subcutaneous injection of lecithin as an extremely effective means of sustaining and increasing the vitality, as it provides a substance urgently needed by the organism in certain conditions. Lecithin derived from brain substance is liable to contain toxic neurins, ptomaines, etc., consequently he prefers the whites of fresh eggs for the purpose. They contain fully 10 per cent. of lecithin. He injects it in emulsion in physiologic salt solution, in a dose of 20 to 30 eg. a day or even more.

90. Closure of Defect in Gall Bladder.—Baldassari has experimented on dogs and found that perforations and lacerations of the gall bladder can be advantageously closed by a

sacro-muscular flap from the abdominal wall. The striped muscular layer turned inward forms a strong wall for the gall bladder, and the layer of peritoneum outside blends with the peritoneum investing the organ. The conditions were found extremely satisfactory when the animals were killed later, and indicate that this method of treating such defects is very promising.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE MEDICAL NEWS VISITING LIST FOR 1903. Weekly (Dated, for 30 Patients); Monthly (Undated, for 120 Patients Per Month); Perpetual (Undated, for 30 Patients Weekly Per Year); and Perpetual (Undated, for 60 Patients Weekly Per Year). The First Three Styles contain 32 Pages of Data and 160 Pages of Blanks. The 60-Patient Perpetual Consists of 256 Pages of Blanks. Each Style in One Wallet-Shaped Book, with Pocket, Pencil and Rubber. Seal Grain Leather, \$1.25. Thumb-Letter Index, 25 Cents Extra. Philadelphia and New York: Lea Brothers & Co.

HUMAN ANATOMY. A Complete Systematic Treatise by Various Authors, Including a Special Section on Surgical and Topographical Anatomy. Edited by Henry Morris, M.A., and M.B. Lond., F.R.C.S. Eng., Member of the Council (Late Vice-President) of the Royal College of Surgeons of England. Illustrated by 846 Wood Cuts, the Greater Part of Which are Original and Made Expressly for This Work by Special Artists, 266 Printed in Colors. Third Edition, Revised and Enlarged. Cloth. Pp. 1328. Price, \$6.00. Philadelphia: P. Blakiston's Son & Co. 1902.

THE WORK OF THE DIGESTIVE GLANDS. Lectures by Professor J. P. Pawlow, Director of the Physiological Department of the Institute for Experimental Medicine. Translated into English by W. H. Thompson, M.D., M.Ch., F.R.C.S. (Eng.), King's Professor of the Institute of Medicine, Trinity College, Dublin. Illustrated. Cloth. Pp. 196. Price, \$2.00. London: Charles Griffin & Co., Ltd. Philadelphia: J. B. Lippincott Co. 1902.

A TREATISE ON DISEASES OF THE EYE, NOSE, THROAT AND EAR. For Students and Practitioners. By Various Authors. Edited by William Campbell Posey, A.B., M.D., Professor of Ophthalmology in the Philadelphia Polyclinic, and Jonathan Wright, M.D., Attending Laryngologist to Kings County Hospital. Illustrated with 650 Engravings and 35 Plates in Colors and Monochrome. Cloth. Pp. 1238. Price, \$7.00. Philadelphia and New York: Lea Brothers & Co. 1903.

NOETHAGEL'S PRACTICE OF MEDICINE: American Edition. Diseases of the Bronchi. By Dr. F. A. Hoffmann, of Leipzig. Diseases of the Pleura. By Dr. O. Rosenbach, of Berlin. Pneumonia. By Dr. F. Aufrecht, of Magdeburg. Edited with Additions, by John H. Musser, M.D., Professor of Clinical Medicine, University of Pennsylvania. Seven Full-Page Colored Lithographic Plates. Pp. 1030. Cloth. Price, \$5.00 net. Philadelphia and London: W. B. Saunders & Co. 1902.

THE AMERICAN TEXT-BOOK OF OBSTETRICS. In Two Volumes. Edited by Richard C. Norris, M.D.; Art Editor, Robert L. Dickinson, M.D. Second Edition, Thoroughly Revised and Enlarged. Vols. I and II. Cloth. Pp. 547 and 554 respectively. Colored and Half-tone Plates. Price, Per Set, \$7.00. Philadelphia and London: W. B. Saunders & Co. 1902.

A TEXT-BOOK OF THE DISEASES OF THE EAR. For Students and Practitioners. By Professor Dr. Adam Politzer, of Vienna. Translated at the Personal Request of the Author, and Edited by Milton J. Ballin, Ph.B., M.D., and Clarence L. Heller, M.D. Fourth Edition, Revised and Enlarged, with 346 Original Illustrations. Cloth. Pp. 884. Price, \$7.50. Philadelphia and New York: Lea Brothers & Co. 1903.

TEXT-BOOK OF MEDICAL JURISPRUDENCE AND TOXICOLOGY. By John J. Reese, M.D., Late Professor of Medical Jurisprudence and Toxicology in the University of Pennsylvania. Sixth Edition. Revised by Henry Leffmann, A.M., M.D., Professor of Chemistry and Toxicology in the Woman's Medical College of Pennsylvania. Cloth. Pp. 660. Price, \$3.00 net. Philadelphia: P. Blakiston's Son & Co. 1902.

DISEASES OF THE PANCREAS AND THEIR SURGICAL TREATMENT. By A. W. Mayo Robson, F.R.C.S., Senior Surgeon, Leeds General Infirmary; and B. G. A. Moynihan, M.S. (Lond.), F.R.C.S., Assistant-Surgeon, Leeds General Infirmary. 293 Pages, illustrated. Cloth. Pp. 293. Price, \$3.00 net. Philadelphia and London: W. B. Saunders & Co. 1902.

CLINICAL SURGERY for the Instruction of Practitioners and Students of Surgery. By A. J. Ochsner, B.S., F.R.M.S., M.D., Chicago, Surgeon-in-Chief, Augustana Hospital and St. Mary's Hospital. Pp. 481. Price, Cloth, \$6.00; Leather, \$7.00. Chicago: Cleveland Press (The Clinical Review Publishing Co.).

BACTERIOLOGICAL TECHNIQUE. A Laboratory Guide for the Medical, Dental, and Technical Student. By J. W. H. Eyre, M.D., F.R.S. Edin., Bacteriologist to Guy's Hospital. With 170 Illustrations. Cloth. Pp. 375. Price, \$2.50 net. Philadelphia and London: W. B. Saunders & Co. 1902.

MEMORANDA ON POISONS. By Thomas Hawkes Tanner, M.D., F.L.S. Ninth Revised Edition, by Henry Leffmann, A.M., M.D., Professor of Chemistry in the Woman's Medical College of Pennsylvania. Cloth. Pp. 177. Price, \$0.75. Philadelphia: P. Blakiston's Son & Co. 1902.

THE PHYSICIAN'S POCKET ACCOUNT BOOK, Consisting of a Manila-Bound Book of 208 Pages and a Leather Case. By J. J. Taylor, M.D. Price, \$1.00 Complete. Subsequent Books to Fill the Case 40 Cents Each, or 3 for \$1.00. Philadelphia: Published by The Medical Council.

SPECTACLES AND EYEGLASSES: Their Forms, Mounting and Proper Adjustment. By R. J. Phillips, M.D., Ophthalmologist, Presbyterian Orphanage. Third Edition, Revised with 52 illustrations. Cloth. Pp. 109. Price, \$1.00. Philadelphia: P. Blakiston's Son & Co. 1902.

THE DEVELOPMENT OF THE HUMAN BODY. A Manual of Human Embryology. By J. Playfair McMurrich, A.M., Ph.D., Professor of Anatomy in the University of Michigan. With 270 illustrations. Cloth. Pp. 527. Price, \$3.00. Philadelphia: P. Blakiston's Son & Co. 1902.

THE STORY OF A LIVING TEMPLE. A Study of the Human Body. By Frederick M. Rossiter, B.S., M.D., and Mary Henry Rossiter, A.M. Cloth. Pp. 348. Price, \$1.00 net. Chicago, New York and Toronto: Fleming H. Revell Co. 1902.

REPORT OF THE SURGEON-GENERAL U. S. NAVY, Chief of the Bureau of Medicine and Surgery to the Secretary of the Navy, 1902. Paper. Pp. 339. Washington: Government Printing Office. 1902.

STUDIES FROM THE DEPARTMENT OF PATHOLOGY OF THE COLLEGE OF PHYSICIANS AND SURGEONS, Columbia University, N. Y. Vol. VIII. For the Collegiate Year 1901-2. Paper.

TRANSACTIONS OF THE WEST VIRGINIA STATE MEDICAL ASSOCIATION. Instituted April 10, 1867. Paper. Wheeling: Daily Intelligencer Steam Job Press. 1902.

THE MEDICAL RECORD VISITING LIST OR PHYSICIANS' DIARY FOR 1903. New Revised Edition. Leather. Price, \$1.25. New York: Wm. Wood & Co. 1902.

EIGHTH ANNUAL REPORT OF THE CHICAGO BUREAU OF CHARITIES, for the Fiscal Year Ending May 31, 1902. Paper. Pp. 39.

TRANSACTIONS OF THE MEDICAL SOCIETY OF NEW JERSEY, 1902. Cloth. Pp. 291. Newark, N. J.: L. F. Hardham. 1902.

The Public Service.

Army Changes.

Movements of Medical Officers, U. S. Army, under orders from the office of the Adjutant-General, Washington, D. C., from Nov. 8 to 15, 1902, inclusive:

Arthur, Wm. H., major and surgeon, U. S. A., having arrived in San Francisco, will report to this city and report in person to the Surgeon-General of the Army for instructions.

Branch, Frederick D., captain and asst.-surgeon, U. S. V., is honorably discharged, to take effect Dec. 20, 1902, his services being no longer required.

Garlington, Joseph C., captain and asst.-surgeon, U. S. V., is honorably discharged, to take effect Nov. 30, 1902, his services being no longer required.

Heller, Joseph M., major and surgeon, U. S. V., is honorably discharged, to take effect Nov. 30, 1902, his services being no longer required.

Hoff, John Van R., lieutenant-colonel and deputy surgeon-general, U. S. A., is relieved from duty in the office of the Surgeon-General of the Army, to take effect Dec. 1, 1902, and will then proceed to Ft. Leavenworth, Kan., and report in person to the commanding officer of that post for duty.

Kemp, Jos. M., contract surgeon, U. S. A., will proceed from this city to San Francisco, and will report to the commanding general, Department of California, for transportation to the Philippine Islands.

The resignation of Arthur M. Line, first lieutenant and asst.-surgeon, U. S. A., of his commission as an officer of the Army has been accepted by the President, to take effect Dec. 1, 1902.

Lynch, Charles, major and surgeon, U. S. V., captain and asst.-surgeon, U. S. A., is honorably discharged from the service of the U. S. as major and surgeon, U. S. V., only, to take effect Dec. 15, 1902.

Lynch, Charles, major and surgeon, U. S. V., now at San Francisco, will proceed to Ft. Porter, N. Y., for duty.

Nicholson, John L., contract surgeon, U. S. A., is relieved from duty at Monterey, Cal., and will proceed to his home, Dorchester, Mass., and report to the Surgeon-General of the Army for annulment of contract.

Tweedle, Hedley V., contract surgeon, U. S. A., is relieved from duty at the General Hospital, San Francisco, and will proceed to Monterey, Cal., for duty.

Phillips, John L., major and surgeon, U. S. A., having reported his arrival in San Francisco, will report in person to Major-General Adna R. Chaffee, U. S. A., for special duty and to accompany him to his station and upon completion of this duty will report by letter to the Adjutant-General of the Army for further orders.

Shaw, Henry A., captain and asst.-surgeon, U. S. A., is granted leave of absence for ten days.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Nov. 15, 1902:

Medical Inspector J. R. Waggoner, detached from the Marine Recruiting Station, Boston, and ordered to the Navy Yard, Mare Island, Cal.

Surgeon J. W. Baker, retired, ordered to duty at the Naval and Marine Recruiting Stations, Boston.

Surgeon N. H. Drake, detached from the Navy Yard, Mare Island, Cal., and to continue duty on *Solacc*.

P. A. Surgeon J. M. Moore, detached from the *Indiana*, and ordered to the *Raleigh*, when commissioned.

Medical Director G. F. Winslow, detached from the Naval Recruiting Station, Boston, and to wait orders.

A. A. Surgeon H. Shaw, appointed asst.-surgeon from October 28.

P. A. Surgeon A. W. Dunbar, detached from the Navy Yard, Puget Sound, Wash., and ordered to the *Wyoming* when commissioned.

P. A. Surgeon A. R. Alfred, ordered to the Navy Yard, Puget Sound, Wash.

P. A. Surgeon E. J. Grow, detached from the Navy Yard, New York, and ordered to the *Marblehead*.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Nov. 13, 1902:

Assistant Surgeon-General H. D. Geddings, to proceed to Delaware Breakwater quarantine for special temporary duty.

Surgeon John Godfrey, granted leave of absence for one month from November 13.

Surgeon W. P. McIntosh, granted leave of absence for 3 days from November 27.

P. A. Surgeon G. M. Guiteras, to proceed to Reedy Island quarantine for temporary duty, relieving Asst.-Surgeon T. F. Richardson.

P. A. Surgeon J. H. Oakley, granted leave of absence for one day.

P. A. Surgeon H. W. Wickes, to proceed to Cleveland, Ohio, and assume temporary charge of the service during the absence on leave of P. A. Surgeon J. B. Greene.

P. A. Surgeon J. B. Greene, granted leave of absence for 15 days from November 22.

Asst.-Surgeon V. G. Helser, to proceed to Philadelphia and report to medical officer in command for special temporary duty.

Senior Pharmacist and Chemist W. F. Macdowell, relieved from temporary duty in Washington, D. C., and directed to proceed to New York, and report to Surgeon G. W. Stoner, Immigration Depot, for duty, relieving Senior Pharmacist and Acting Chemist A. M. Roehrig.

Senior Pharmacist and Acting Chemist A. M. Roehrig, on being relieved from duty at the Immigration Depot, New York, to proceed to Stapleton and report to medical officer in command for duty and assignment to quarters, relieving Senior Pharmacist Charles Miller.

Senior Pharmacist Charles Miller, on being relieved from duty at New York (Stapleton), to proceed to Pensacola, Fla., and report to the acting assistant-surgeon in charge of the Santa Rosa quarantine station for temporary duty.

BOARDS CONVENED.

Board convened at Washington, D. C., for the consideration of the Act of Congress approved July 1, 1902, entitled "An act to regulate the sale of viruses, serums, toxins and analogous products in the District of Columbia, to regulate interstate traffic in said articles, and for other purposes." Detail for the Board: Assistant Surgeon-General L. L. Williams, chairman; Assistant Surgeon-General H. D. Geddings; P. A. Surgeon M. J. Rosenau; Asst.-Surgeon B. S. Warren, recorder.

Board convened at the U. S. Marine Hospital, Chelsea, Mass., Nov. 17, 1902, for the physical examination of officers of the Revenue Cutter Service. Detail for the Board: Surgeon R. M. Woodward, chairman; Asst.-Surgeon W. K. Ward, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Nov. 15, 1902:

SMALLPOX—UNITED STATES.

California: San Francisco, Oct. 26-Nov. 2, 6 cases.
Colorado: Denver, Oct. 25-Nov. 1, 3 cases.
Florida: Jacksonville, Nov. 1-8, 1 case; Lamont, Oct. 18-Nov. 8, 4 cases; Mayport, Oct. 18-Nov. 8, 1 case; Pensacola, Oct. 18-Nov. 8, 1 case.
Illinois: Nov. 1-8, Chicago, 3 cases, 1 death; Freeport, 4 cases.
Indiana: Indianapolis, Nov. 1-8, 2 cases.
Kentucky: Lexington, Nov. 1-8, 13 cases.
Massachusetts: Nov. 1-8, Boston, 8 cases, 1 death; Cambridge, 1 case; Medford, 1 case.
Michigan: Detroit, Oct. 25-Nov. 8, 20 cases; Grand Rapids, Nov. 1-8, 4 cases.
Missouri: St. Louis, Nov. 2-9, 19 cases.
Nebraska: Omaha, Nov. 1-8, 1 case.
New Hampshire: Nov. 1-8, Manchester, 2 cases; Nashua, 20 cases.
New York: New York, Nov. 1-8, 4 cases, 1 death.
Ohio: Cincinnati, Oct. 31-Nov. 7, 4 cases; Cleveland, Nov. 1-8, 12 cases, 5 deaths; Hamilton, Nov. 1-8, 1 case; Toledo, Oct. 4 Nov. 8, 14 cases, 2 deaths; Warren, Oct. 25-Nov. 1, 1 case.
Pennsylvania: Nov. 1-8, Altoona, 1 case; Erie, 8 cases; Johnstown, 5 cases, 1 death; Philadelphia, 3 cases; Pittsburgh, Oct. 25 Nov. 8, 52 cases, 8 deaths.
South Dakota: Sioux Falls, Nov. 1-8, 1 case.
Utah: Salt Lake City, Nov. 1-8, 1 case.
Wisconsin: Milwaukee, Nov. 1-8, 20 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Oct. 18-25, 8 cases.
Belgium: Antwerp, Oct. 18-25, 1 case, 1 death.
Brazil: Bahia, Sept. 27-Oct. 18, 4 cases.
Chile: Pisagua, Oct. 13, 6 cases.
Ecuador: Guayaquil, Oct. 18-25, 3 deaths.
Great Britain: Bristol, Oct. 11-18, 1 death; London, Oct. 18-25, 1 case, 1 death; Manchester, Oct. 18-25, 1 case.
Russia: Oct. 11-18, Moscow, 3 cases; Odessa, 1 case.
Switzerland: Geneva, Oct. 11-18, 1 case.

YELLOW FEVER.

Colombia: Panama, Oct. 27-Nov. 3, 6 cases.
Costa Rica: Port Limon, Oct. 25-Nov. 1, 2 cases, 2 deaths.
Ecuador: Guayaquil, Oct. 18-25, 2 deaths.
Mexico: 24, 1 case, 1 death; Tampico, Oct. 26 Nov. 2, 5 Oct. 25-Nov. 1, 7 cases, 5 deaths.

CHOLERA—INSULAR.

Philippine Islands: Manila, Sept. 14-20, 49 cases, 36 deaths; Provinces, Sept. 13-20, 3,853 cases, 2,454 deaths.

CHOLERA—FOREIGN.

Egypt: July 12, 38,083 cases, 32,377 deaths; Oct. 25-Nov. 1, 225 cases, 22 deaths; Alexandria, Oct. 11-18, 58 cases, 55 deaths.
Japan: Kobe, Oct. 4-11, 49 cases, 22 deaths.

PLAGUE—UNITED STATES.

California: San Francisco, Oct. 28, 1 case, 1 death.

PLAGUE—FOREIGN.

India: Karachi, Oct. 5-12, 13 cases, 8 deaths.
Russia: Odessa, Oct. 18-25, 45 cases, 16 deaths.

THE TREATMENT OF TUBERCULAR GLANDS OF THE NECK.*

LEONARD FREEMAN, M.D.

Professor of Surgery Denver and Gross Medical College; Surgeon
to Arapahoe County Hospital, St. Joseph's Hospital
and Jewish National Hospital.

DENVER.

In Colorado everything pertaining to tuberculosis is of such importance that I have no hesitation in presenting this subject for your consideration, particularly as it has not been previously discussed in this society—so far as I am aware.

GENERAL CONSIDERATIONS.

The neck, as a whole, contains several hundred lymph glands, some of them superficial and some deep. Although their distribution is general, they exist principally in definite groups. Certain of these groups are particularly liable to tubercular disease, owing to their close connection with the entrance points of infection, such as the tonsils, teeth and pharynx. Chronic otitis, eczema of the scalp, ophthalmia, and various nasal troubles are also sources of infection, while in isolated instances germs may be deposited from the blood or ascend from the bronchial lymphatics.

It is a progressive disease, one gland sooner or later infecting others, a point of importance in selecting a rational form of treatment. The nodes most frequently affected are those in the submaxillary region and those lying along the internal jugular vein, in front of, behind and beneath the sterno-mastoid muscle. The submental and parotid regions are at times implicated, as well as the areas in the vicinity of the mastoid and above the clavicle. Towards the back of the neck infection is less frequent. The seriousness of tuberculosis of the cervical lymphatic system is generally underestimated. Chronic swellings in the neck are so common that they are not given the attention they deserve. To be sure, the danger is much less than in pulmonary affections, but, nevertheless, the enemy is there and prepared to invade some vital organ if opportunity arise. A considerable proportion of cases, from 10 to 25 per cent. according to Dowd, develop phthisis; while some die of meningitis or of general tuberculosis, and in others tubercular foci appear in various parts of the body. (A short time ago, for instance, I examined a boy of five with hip-joint disease closely following enlargement of the cervical lymphatic glands). To these dangers must be added the chances of repulsive deformity and unsightly scars.

Treatment is both general and local, the latter being divided into non-operative and operative.

GENERAL TREATMENT.

This is of the utmost importance, and is always indicated, sometimes for its curative effects in the early stages, but more frequently as a safeguard against relapse following an operation. It comprises both medicinal and hygienic measures.

Medicinal.—Under this head come principally cod-liver oil, the syrup of iodid of iron, the hypophosphites, creosote, guaiacol, etc., although it is questionable that much effect is obtained from any of them. The various forms of tuberculin are not only ineffective, but by some are considered dangerous when used for a longer time than is required to establish a doubtful diagnosis.

The employment of cinnamic acid and other so-called specifics has not been attended by sufficient success to justify their general recommendation. As far as can be judged at present, the question of medication seems to be more nearly related to a building up of the resisting powers of the patient than to any specific drug action upon the germ.

Hygienic.—Most cases of tubercular adenitis develop in the young under bad hygienic surroundings—in the slums, tenements and sweatshops of large cities, and wherever people are overcrowded, overworked and underfed, with lack of sleep, fresh air and sunshine. Hence, if we wish to obtain favorable results in the cure of the disease and in the prevention of relapse, too much attention can not be given to hygienic measures. In fact, these are relatively of as much importance as in the treatment of pulmonary lesions.

It has long been observed that these patients do remarkably well at seaside resorts—for instance, at Berck-sur-Mer, as reported by Calot. So thoroughly is this recognized that seaside governmental stations have been advocated. I believe, however, that a high, dry climate, such as that of Colorado, offers more advantages than the seashore in the treatment of surgical tuberculosis. It is well established, for instance, that tubercular bone lesions are much less frequent in Colorado than in most lower altitudes; and although I can give no statistics, I have reason to think this is true of glandular tuberculosis also. During a surgical experience of over seven years in Colorado, I have seen nowhere near so many glandular enlargements as I observed in an equal length of time in Cincinnati; and the cases have not been, on an average, so virulent. In short, there is reason to presume that our rarefied, dry and stimulating atmosphere, our sunshine, and our relatively outdoor existence, do more toward fortifying the resisting power of the body against lymphatic tuberculosis than does a residence at the seashore; a fact which we have

* Read before the Colorado State Medical Society at Pueblo, June 25, 1902.

long recognized, but have failed to emphasize as it deserves, our principal attention having been directed to troubles of a pulmonary nature.

LOCAL TREATMENT.

Non-Operative.—In order to promote cure and prevent relapse, it is of prime importance to abolish, if possible, the sources of infection—by attention to teeth, tonsils, pharynx and nose, and by the eradication of inflammations of the ears and scalp. The importance of the teeth has been demonstrated by Starck and by Koerner, the former finding decayed teeth in 41 per cent. of cases and the latter in 73.8 per cent. Starck also detected tubercle bacilli in old cavities in several instances. Goodale even asserts that many enlarged glands can be made to disappear merely by treating the tonsils with solutions of iodine, but this has not been substantiated to any extent by others.

Massage and such methods as crushing of the glands between the fingers or their subcutaneous division with small knives have been abandoned as ineffective and dangerous, because favoring local and general dissemination.

Ointments and counter-irritants are still in extensive use, although their utility is, to say the least, doubtful. As ointments, ichthyol, resorcin, and the iodide of lead are probably the best. The most reliable counter-irritants are tincture of iodine and green soap.

Trojanow, who has had a large experience with various forms of local treatment, places more faith in the application of heat (hot-water bag for an hour or two each day) than in anything else, but nevertheless, his results have not been brilliant.

The x-ray has not yet had its utility established, although some encouraging cures have been reported.

The interstitial injection treatment has been advocated for many years. Some substances are employed for their supposed direct curative effects, such as tincture of iodine (5 to 10 drops every four days); Fowler's solution in increasing doses (8-10-12 drops); solutions of carbolic acid, alcohol, acetic acid, nitrate of silver, corrosive sublimate, guaiacol, phosphate of iron, etc. Also camphorated naphthol, balsam of Peru, oil of cinnamon, cinnamic acid, iodoform, etc. Other substances, such as chlorid of zinc (2 to 10 per cent.), stronger solutions of carbolic acid, papain, etc., are used for the purpose of causing a rapid breaking down of the glandular substance, which is supposed to facilitate more effective treatment. The method of Calot, for instance, is to inject 2 per cent. chlorid of zinc, with a hypodermic syringe, every second day, until purulent softening takes place. The fluid is then aspirated and replaced with camphorated naphthol.

These procedures, although strongly advocated by their supporters, have given rise to disappointment in the hands of others. They are unreliable and not free from discomfort and ever danger, as proven by cases of poisoning from camphorated naphthol.

Iodoform (10 per cent.) dissolved in ether (Verneuil) or suspended in olive oil or glycerin (Krause), probably forms the best material for injection. The oil must be boiled and cooled; and before stirring in the iodoform, it must be sterilized by soaking for twenty-four hours in 1-1000 corrosive sublimate. Into glands which have not yet broken down, about half a hypodermic syringe is inserted every eight to ten days, while glands containing fluid are aspirated and then filled with the emulsion. Even this method leads to more failures than successes and wastes time.

In estimating the value of the injection treatment, it must not be overlooked that although certain glands

may disappear, there are nearly always others which can not be reached, or even recognized without a surgical operation, and these are only too apt to give rise to trouble in the future.

Electrolysis and the use of electricity in other ways have never attracted much attention, and the same may be said of subcutaneous curettement.

The concurrence of medical and surgical opinion is that the non-operative treatment of tubercular adenitis is unsatisfactory, except in incipient cases, where the glands are still small, movable and undegenerated; but these are the cases which, like the early stages of cancer, are seldom seen.

Operative Treatment.—The majority of cases are best treated by operation, unless the general condition of the patient forbid. The presence of tuberculosis elsewhere, even in the lungs, is, however, no contra-indication, except when far advanced. If operation were refused all consumptives in Colorado, as has been advised in the East and abroad, much injustice would be done both patient and surgeon. Every-day experience shows that phthisic cases take chloroform so well, at least in Colorado, that little danger is to be anticipated from its use, and the removal of glands may give a much needed impetus towards recovery.

Curettement is applicable to sinuses, to tubercular ulcers of the skin, to cases in which during a radical operation the extirpation of a gland is attended by too much danger, and to cases where the condition of the patient precludes extensive surgical intervention.

The results are good provided all the diseased tissue can be removed; hence, the greater the disintegration of the glands the better. It is at times almost impossible, however, to scrape away all the tough glandular substance from within its adherent capsule, and to go outside this barrier may be dangerous in the extreme.

The method has its shortcomings, and must be employed with caution. It is easy, for instance, to scrape a hole in the internal jugular, which is so often adherent to caseous masses. In addition, it is impossible to reach and destroy all the affected glands, while the excessive traumatism may disseminate the disease.

Cauterization of sinuses, after curettement, with pure carbolic acid, applied with cotton on a probe, and repeated at intervals of a few days, often promotes healing to a decided degree, but the injection of iodoform is of little service. The ragged, undermined and livid tubercular skin around the opening of a sinus must be scraped away in order to facilitate rapid healing.

Although so strongly recommended by Treves, the cauterization of glands by plunging into them the tip of a thermocautery has been practically abandoned in favor of radical operative measures. The same may be said of the use of the seton.

Complete extirpation dates back to the time of Galen, and was extensively practiced by Parré and Larrey. It may be easy or it may be one of the most difficult operations in surgery. Nearly always many more glands must be removed than were counted on beforehand. They often appear one after another in the wound in apparently endless profusion, so that what promised to be a simple excision of one or two movable lymph nodes turns out to be an extensive, complicated and serious intervention. No one should attempt an operation of this kind lightly, without a thorough knowledge of the anatomy of the parts, and a full command of the best surgical technic.

When the operation is once begun, it should be made as complete as possible. If any diseased glands are left

they are likely to give rise to future disturbance, although the slightly affected ones may, under proper hygiene, remain quiescent. This is fortunate, because it may be impracticable to follow all the eccentric ramblings of the tubercle bacillus throughout the intricate maze of lymphatic structures in the cervical region, Betagh even claiming that the fat is sometimes infected.

In simple cases, where a single movable gland or a small bunch of glands is to be removed, a short incision is sufficient, which can be stretched, if necessary. Transverse scars, although often objectionable for other reasons, have less tendency to spread and become hypertrophied than longitudinal ones. Transverse scars in the submaxillary region are at times almost invisible.

But in the majority of instances, where operations are required at all, they must be so extensive that small incisions are out of the question. No greater surgical indiscretion can be made than to attempt to remove a number of enlarged, matted and adherent glands through a small opening. Plenty of room must be secured, even at the expense of extensive scars.

Incisions of many forms have been devised by various operators. Nearly all are efficient so far as room is concerned, but many occasion unnecessary disfigurement. This is sometimes true of the "S"-shaped incisions of Hartley and of Senn, which pass transversely beneath the jaw to a point beyond the mastoid, then curve downwards and forwards across the sterno-mastoid, and finally backwards parallel to the clavicle. In most instances enough room is obtained by a transverse submaxillary cut extended in a curve over the upper portion of the sterno-mastoid and then straight down along its posterior border. If, however, according to Dowd, the horizontal incision is carried backwards to the hair, and then curved downwards along its edge, a large skin-flap is formed which gives excellent approach to the enlarged glands. If necessary, the incision may be curved forward above the clavicle. The resulting scar is not conspicuous, especially from the front.

Dollinger advocated operating through an incision placed entirely within the hair back of the ear, which is undoubtedly possible in selected cases, but desirable in very few, on account of difficulty and danger.

The slightest consideration makes it evident that no formal incision can be universally employed. The skin must be divided to suit the case—sometimes in one direction, sometimes in another, following natural lines of cleavage and concealing scars as much as is consistent with thoroughness and safety. The subcutaneous suture should be used whenever practicable, as it not only does away with unsightly stitch holes, but prevents the annoying turning in of the edges of the skin.

Although the division of the sterno-mastoid muscle, with subsequent reunion, facilitates ease and safety in operating, it is seldom necessary and should be avoided, if possible, as it may lead to deformity. Retraction of the muscle is usually all that is required.

Theoretically, it is best to remove the glands, their capsules and surrounding fatty tissue in one mass. Practically this is not always possible. Portions of capsule or even of glands may have to be left behind rather than run the risk of injuring important structures. Even in the most skilled hands these operations are frequently so long and tedious as to try the patience and endurance of the operator to the utmost.

The *jugular vein* should be at once exposed in difficult cases, either above or below the glandular mass. Its situation is then known, and it can be freed from abnormal attachments with considerable safety. It is

seldom necessary, as advocated by Stiles and others, to divide the vein between ligatures and remove a section along with the diseased tissues, or even to apply temporary ligatures with the idea of tightening them if required.

Injury to the jugular is not very uncommon. It generally occurs while the tissues are being pulled upon, thus stretching the vein and emptying it of blood, when it is easily mistaken for fascia and divided. Hence it is advisable to relax all deeper tissues before cutting.

Hemorrhage from a wounded jugular is alarming, but seldom fatal, for it can easily be controlled by pressure until ligatures, forceps or sutures have been applied. It is sometimes wise to leave the forceps *in situ*. The greatest danger, perhaps, lies in the entrance of air into the circulation. I have seen this on two occasions and fully realize its importance. Prompt closure of the opening with a finger is the best safeguard. The carotid arteries are much less liable to injury than the jugular vein, because their walls are thicker and their presence more readily detected by their pulsations.

Various nerves, however, must be constantly watched for by the operator. The one most exposed to injury is the spinal accessory, as it emerges from the sterno-mastoid muscle near the center of its posterior border. Although denied by some (Milton), the division of this nerve usually results in more or less atrophy and paralysis of the trapezius, which is noticeable in inequality of the shoulders and impairment of motion. If the divided ends are reunited with catgut, function may be restored within a few days. In one case I was unfortunate enough to cut this nerve in two places. Immediate suturing resulted in the reappearance of power in the trapezius within a week. In another instance about ten days elapsed before the shoulder could be spontaneously elevated. In the light of personal experience, I should not hesitate to deliberately divide the spinal accessory, when necessary, with the idea of reuniting it before completing the operation. It is readily detected by rubbing some blunt instrument firmly across the wound and noting the jerking of the shoulder when the nerve is touched.

The pneumogastric, phrenic, laryngeal and sympathetic nerves are well out of the way in most operations and are seldom injured. Division of the phrenic is a serious accident, but the pneumogastric and sympathetic may be cut without disaster. Injury to the facial nerve, followed by paralysis, is an unfortunate occurrence which may arise during the removal of glands in the neighborhood of the parotid. The inferior maxillary branch supplying the lower lip and adjacent parts may be cut while working in the submaxillary region, although this will not occur unless the bone is encroached on too closely. An unpleasant distortion of the corner of the mouth results, especially in talking. This may correct itself, as claimed by Dowd. If it does not, it has been suggested that the deformity can be mitigated by dividing the nerve of the opposite side. This is accomplished by slipping a tenotome from below under the tissues covering the jaw anterior to the facial artery, and severing the nerve against the bone.

Adhesions of glands to nerves and vessels may often be suspected because of various pressure symptoms, such as pain and numbness in the arm, engorgement of facial veins, weakness of the temporal pulse, etc.

When removing glands in the lower portion of the neck it is possible to injure the pleura, and, on the left side, the thoracic duct. Injury to the duct may not be noticed at the time, but manifest itself later by an

abundant flow of lymph. It is best managed by packing and often recovers.

It is wise to avoid division of skin nerves, but this is not often possible, so that anesthetic areas about the ear, for instance, frequently follow an operation. They tend to disappear in time.

Riedel's claim that the removal of too many glands from a given region may result in more or less permanent edema is scarcely tenable, as the connective tissue lymph spaces soon form an adequate collateral circulation (Bayer).

Drainage to prevent the accumulation of blood and serum is desirable, although it may be dispensed with in twenty-four hours. Dressings should exert as much pressure as is tolerable, by means of properly placed pads of gauze and a well-adjusted bandage. Plaster-of-paris casts or supporting sandbags are unnecessary. The lavage of large cervical wounds with strong antiseptics is not advisable because of the occasional powerful action on important nerve structures.

Especial care must be given to anesthesia, as there is once in a while a marked tendency to stoppage of respiration, although I have failed to notice this to the extent emphasized by Finkelstein.

The necks of those who have suffered from tubercular glands are apt to be disfigured by unsightly scars, which may be corrected by excision, skin grafting or filling depressions with paraffin. There is an unfortunate tendency, especially in tubercular lymphadenitis, for scars to become red and hypertrophied—a sort of false keloid. Sometimes this is unavoidable; but again it appears to be due to irritation of the immature cicatrix, and may be prevented by adequate protection of the part. Removal of such scars may be followed by recurrence.

STATISTICS OF OPERATIVE TREATMENT.

The exact percentage of complete cures following radical operations is difficult to obtain, for most cases soon disappear from observation. The available figures vary markedly. Wohlgemuth, for instance, reports 70 per cent., Hobel 68 per cent., and Von Noorden 62.4 per cent.—an average of 65 per cent. in 309 cases. Bloss, on the other hand, places the number of cures at 46 to 48 per cent., while Billroth obtained but 24 per cent.

The mortality, when the operations are skilfully done, is surprisingly low, most of the fatalities, as in goiter, being due to pulmonary complications. Too much should not be attempted at one time, and it is often better to operate in two sittings rather than attack both sides of the neck at once.

My own cases, although considerable in number, are neither numerous enough, nor have they been sufficiently well followed up, to permit of the drawing of reliable conclusions. My belief is decided, however, that radical operation is not only justifiable, but strongly indicated, in all serious or obstinate cases. And it must not be forgotten that better results can be obtained in Colorado than in lower, less favorable localities, because the chances of relapse are not so great.

SUMMARY.

1. The gravity of tuberculosis of the cervical lymphatics, both as regards local deformity and remote secondary manifestations, is generally underestimated.

2. General treatment, especially hygiene, is of the utmost importance, both in the cure of incipient trouble and in the prevention of relapses following operations on more advanced cases, most recurrences being due to neglect of such measures.

3. Residence at the seashore has long been recognized as of great benefit; but there is reason to believe that a high and dry climate, such as that of Colorado, with its rarefied, stimulating atmosphere and abundant sunshine, possesses superior advantages.

4. A point of extreme importance in local treatment is to abolish sources of infection, in the teeth, tonsils, nose, ear, scalp, etc., and neglect of this is apt to result in failure.

5. Non-operative treatment is often of doubtful utility, except in the beginning of the disease.

6. Pulmonary involvement does not contra-indicate operation, at least in Colorado, except in advanced cases.

7. Curettement is applicable to sinuses, tubercular ulcers of the skin, and where complete removal would be attended by too much risk. In all other instances a thorough operation should be done.

8. The size and shape of the incision should be adapted to the particular case. It should be free enough to permit of thoroughness and safety.

9. The chance of permanent cure following operation is probably better in Colorado than in lower and less favorable altitudes.

SANATORIUM TREATMENT OF TUBERCULOSIS.

ANALYSIS OF THREE HUNDRED CASES TREATED AT THE UNITED STATES MARINE-HOSPITAL SERVICE SANATORIUM.*

P. M. CARRINGTON, M.D.

SURGEON U. S. M.-H. S.
FORT STANTON, N. M.

My object in this paper will be to show briefly the results obtained in three hundred and three cases of pulmonary tuberculosis treated at Fort Stanton during a period of about two and one-half years by the open-air climatic treatment. In computing the value of these statistics the chronic nature of tuberculosis of the lungs and the comparatively short duration of treatment must be considered; the average length of treatment in the fatal and discharged cases having been something less than six months, including cases in every stage of the disease; in some the history only covered a period of two or three months and in others the disease had existed for years.

In one hundred and forty-two, or nearly 50 per cent., the history of the disease extended over a period of one year or more prior to admission. In a few cases the physical signs indicated lesions slight in extent, and there was little aside from the presence of bacilli in the sputum on which to base a diagnosis, but unfortunately the moderately and far-advanced cases outnumbered the early cases nearly five to one; some were so far advanced as to excite wonder that they were able to survive the journey to the sanatorium, and in one case death occurred at the railway station before the unfortunate patient could be transferred to the sanatorium; the statistics, however, are given you as they stand and, notwithstanding the great predominance of far-advanced cases, it is believed that the results attained will offer some encouragement to those interested in the climatic treatment of tuberculosis of the lungs.

LOCATION, CLIMATE, ETC.

Fort Stanton is located in Lincoln County, New Mex-

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee: Drs. Arthur R. Reynolds, George Cook and Heman Spalding.

ico, and has an elevation of about 6,100 feet above sea level. The annual rainfall is from 14 to 17 inches, and the mean average temperature is 55.6 degrees. The following is the weather observer's record for the year ended April 30, 1902:

Month.	Mean	Mean	Mean	Precipitation.	Cl'dy	Partly	Clear
1901.	Temp.	Max.	Min.	It. & S.	Days.	Days.	Days.
May	57.6	73.2	41.9	0.61	1	15	15
June	56.8	70.0	43.7	1.34	2	3	25

NOTE.—Cloudy means 7/10 to the entire day; partly cloudy means less than 7/10 of the day.

Fort Stanton was formerly a garrisoned post of the United States Army, but had been abandoned for several years when taken charge of by the Marine-Hospital Service, the old barracks and other buildings being remodeled and repaired for use as wards, quarters, etc. It was the first sanatorium established by the National Government for the treatment of tuberculosis.

The buildings were in such a dilapidated condition

Fig. 1.—Officers' quarters.

as to be absolutely uninhabitable when the station was established by executive order of April 1, 1899, and owing to the then distance from the railroad (about 75 miles) there was difficulty in getting workmen and material, and something over six months elapsed before any of the buildings were ready for occupancy, the first patient being received Nov. 18, 1899. We now have accommodations for about 150 patients, but additional buildings are being repaired for use as wards which will increase our capacity to about 225 patients. The sanatorium is now reached via the El Paso-Rock Island Railway; Capitan, seven miles distant, being our nearest railroad station.

We have our own ice and cold-storage plants, a fully equipped steam laundry and a modern system of plumbing, water works and sewage.

In establishing a sanatorium for consumptives at Fort Stanton it was the intention of Surgeon-General Wyman that the station should, in time, become in large measure self-supporting. With irrigation all kinds of farm and garden products grow luxuriantly and, while it is aside from the purpose of this paper, I may say in passing we produce all of our hay, a considerable portion of our grain and all our garden truck. A herd of Jersey and Holstein cows give us an ample supply of pure, fresh milk and also furnish a portion of our butter.

We are starting a herd of range cattle with the intention of producing our own beef. We also breed horses to a small extent, raise chickens, pigeons, hogs and Belgian hares.

The industrial character of our sanatorium enables me to give employment to a considerable number of recovered and convalescent patients, thus retaining them in advantageous climatic and sanitary environment for a longer period than they would otherwise remain. The difficulty, by the way, of retaining patients under treatment and observation for a sufficient length of time is one which we encounter daily; patients unaccustomed to restraint, except while on board ship, soon tire of the necessarily rigid regulations of sanatorium life. The use of alcoholic stimulants is forbidden except as ordered medicinally for a small percentage of cases; this is considered a hardship not long to be borne by those who have been steady and often hard drinkers for many years. The problem of how to keep men, accustomed as they are to the license of large seaports and lake and river cities, interested, amused and satisfied in an arid region is one not easy of solution. Unfortunately for our statistics, those who allow their longing for the delights of city life to curtail their residence in the sanatorium are usually those with fair or good chances of ultimate recovery while the unfavorable cases, almost to a man, remain. Several cases, favorable when discharged against advice, have returned after absences of two to six months, only to swell our mortuary records.

We try to keep the minds of our patients occupied;

Fig. 2.—Surgeon's quarters and assistant-surgeon's quarters

cards, checkers and other indoor games are provided (to be played out of doors as a rule); a few plant flower gardens and some have taken to golf, which affords a very suitable amount of exercise to a large number of ambulant cases. We have a very fair library, which enables many to interest their minds while taking necessary rest. Horseback riding is allowed a limited number of cases which are practically convalescent.

GENERAL STATISTICAL SUMMARY.

From Nov. 18, 1899, until April 30, 1902, the period covered by these statistics, 303 cases of tuberculosis have been treated with the following results: Forty-five patients have died, 9 discharged not improved, 97 discharged improved, 37 discharged apparently recovered, 115 remain under treatment.

Their ages were as follows: Under 25 years, 47; from 25 to 34 years, 118; from 35 to 44 years, 91; from 45 to 54 years, 33, and 14 cases 55 years of age and older.

In 31 cases, or a little over 10 per cent., there was a history of tuberculosis in either father or mother of patient. In 226 cases both lungs were affected and in 77 only one lung was involved. The tubercle bacillus was demonstrated in the sputum of 273 cases, and in 123 other organisms were found, their order of frequency being as follows: *Staphylococcus pyogenes aureus*, *Streptococcus pyogenes*, *Micrococcus tetragenes*, *Sarcina*

aurantiaca, *Leptothrix baccalis*, bacillus of Friedlander. The pneumococcus was absent. Two or more of these organisms were usually found in one specimen. Pulmonary hemorrhage occurred in 117 cases, in 77 before but not after admission, in 12 after but not before, and in 27 both before and after admission, showing that the risk of hemorrhage at this altitude and under conditions prevailing at this sanatorium is not so great as is popularly supposed. In 12 cases, all advanced, the larynx was involved; 46 cases were complicated with syphilis and 36 with malarial fever; in one case the bladder alone was infected, the bacillus being found by guinea-pig experiment; empyema was present in three

Fig 3—Office and laboratory building

cases. Tubercular meningitis occurred in three cases and in three there was involvement of the testicle.

Of the 188 cases who died or were discharged, 45, or 24 per cent., died; 9, or 5 per cent., were discharged unimproved, and 37, or 20 per cent., were discharged apparently cured. Ten fatal cases and 17 improved and unimproved were under treatment less than one month; one death resulted from acute nephritis, one from cerebral hemorrhage and one from syphilis of the

Fig. 4.—Patients camped in front of hospital

brain. Eliminating from the calculation those cases which were under treatment less than one month the percentages would be as follows: Died, 23 per cent.; improved, 53 per cent., and apparently recovered, 24 per cent.

STATISTICS OF THOSE IN THE EARLY STAGE.

The above figures include all cases of tuberculosis treated at this sanatorium during this period and the moderate and far-advanced cases outnumber the early cases by about 5 to 1. In considering these statistics I have divided the cases into two classes: The first stage or early cases in which there was no appreciable consolidation, one or both lungs affected, with or without

bacilli in sputum, with slight or moderate constitutional disturbance and with localized moist râles; the other class includes second and third stages or moderately and far-advanced cases with appreciable consolidation and physical signs attending same, one or both lungs affected, considerable to very severe constitutional disturbance, with or without bacilli in sputum and including those cases in which there was evidence of cavity formation. Of the first class we have treated 54, 40 have died or been discharged and 14 remain under treatment; the family history was positive in 7 and

Fig 5—Tent life

negative in 47 cases, in 30 cases but one lung was involved and in 24 both lungs. tubercle bacilli were found in the sputum of 39 and other organisms in 27. In 50 per cent. of those in which bacilli were not demonstrated in the sputum there was syphilitic infection.

Tuberculin is not used for diagnostic purposes as a routine measure, owing partly to the extreme prevalence of syphilis in the class of people from whom we draw

Fig 6—Pocket sputum flask M-H S pattern

our patients. We have recently begun injecting the sputum of patients, in which the bacilli can not be demonstrated, into the peritoneal cavity of the guinea-pigs, and in the cases in which this was done there were positive results in 66.6 per cent. and negative in 33.3 per cent. Hemorrhage occurred in 8 cases of this series, but in only two after arrival at the sanatorium; in 2 cases pulmonary hemorrhage was the first indication of the existence of the disease. Of the 40 cases of this class in which treatment has terminated, one, or 2.5 per cent., died, death being due to acute nephritis, 2, or 5 per cent., were discharged improved and 20, or 50 per cent., were discharged apparently cured; or, eliminating

10 unimproved and improved cases which were under treatment less than one month, and the percentages are, apparently cured 66.6 per cent., improved 30 per cent., and died 3.3 per cent. Eight of the cases still being treated are convalescent and six are much improved, both physically and in condition of lungs.

The average length of treatment in the 40 discharged cases was 131 days, in the 22 apparently cured cases 213 days.

STATISTICS OF THOSE IN THE SECOND AND THIRD STAGES OR ADVANCED CASES.

The total number treated under this heading was 249; in 24 cases, or something less than 10 per cent., there was a history of tuberculosis in either father or mother; in 196 cases both lungs were involved and in 53 but one lung. The tubercle bacilli were demonstrated in the sputum of 234 cases and other organisms were present in 96 cases, their order of frequency being:

Fig. 7—Steam sputum sterilizer

Staphylococcus pyogenes aureus, *Streptococcus pyogenes*, *Micrococcus tetragenus*

The results of treatment in the above cases were as follows: 44 died, 7 discharged not improved, 80 improved, 17 apparently or clinically cured, 101 remain under treatment at date of this report.

In one of the cases included in the above series the bladder alone was affected and the guinea-pig experiment was used to demonstrate the tubercle bacilli. In one case the diagnosis was not confirmed, 01 tuberculin having failed to produce reaction.

In 109 cases pulmonary hemorrhage occurred during the course of the disease; in 71 cases there was hemorrhage prior to but not after admission and 26 both before and after admission. The larynx was involved in 12 cases and syphilis complicated in 36 cases. Of the 44 fatal cases included in this record 10 were under treatment less than thirty days and one died at the railroad station en route to the sanatorium. One death was caused by

cerebral hemorrhage and one by cerebral syphilis; in the former case the pulmonary lesions had almost entirely healed, and in the latter they were of secondary importance to syphilitic lesions.

Of the 148 cases under this heading, in which treatment has terminated, 44, or 29 per cent., have died, 7, or 5 per cent., were discharged unimproved, 80, or 54 per cent., were discharged improved, and 17, or 11 per cent., have been discharged apparently cured. Eliminating 10 fatal, 2 unimproved and 5 improved cases, which were under treatment less than one month, the percentages are as follows: died, 26 per cent.; not improved, 3 per cent.; improved, 57 per cent., and apparently cured, 13 per cent. The condition of the 101 patients remaining under treatment is as follows: apparently cured, 2; convalescent, much improved, 68; arrested, 21; worse, 10.

There are included in this series 39 cases which were permanently febrile; in 14 the fever was remittent and in 25 intermittent. The average duration of the disease prior to admission was 14 months, and in all but 3 the bacillus was found in the sputum; 9 were under treatment less than one month, 8 less than two months and 22 longer than two months; 30 of these died, 4 were discharged improved and 5 not improved; there was tubercular meningitis in 4 cases, the larynx was involved in 4 and other organs in 5; syphilis was a complication in 11, malaria in 10 and Bright's disease in 5. In 3 death was caused by hemorrhage. While most of our cases had fever at some time during the course of the disease, it usually, if present on arrival, subsided in a few days, but, as will be seen, those cases in which the febrile condition was permanent gave the greatest mortality; the intermittent cases usually showed a normal morning temperature and an evening temperature ranging from 38 to 41 degrees centigrade, the remittent cases usually had a morning temperature of about 38 and an evening temperature of not over 39 degrees; 16 other cases were characterized by subnormal temperatures with an evening rise above normal in 12 and a continued subnormal temperature in 4. The average previous duration of the disease in these cases was twelve and one-half months, and they all remain under treatment at this writing, 14 being improved and 2 not improved. These two groups represent the most unfavorable types of the disease as we see it.

MEASURES TAKEN TO AVOID INFECTION OF THE SANATORIUM.

Under this head the most important item, of course, is the disposal of the sputum of patients. Each patient is provided with a pocket sputum flask and a hand or bedside sputum cup, and they are forbidden to expectorate except into these receptacles, and no patient will be retained at the sanatorium who expectorates in any other place than the cups provided. All metal cups are disinfected by steam each day, the Seabury & Johnson cups being burned. A careful daily check is kept and any patient failing to present his cups for disinfection is at once reported to me for investigation.

While disinfection by steam is effective, there can be no question that destruction by fire is a preferable method, mainly because it is easier and more cleanly. I am now making arrangements to substitute a crematory for the steam disinfection of sputum. The main difficulty heretofore has been the economical construction of a destructible pocket sputum flask of effective pattern.

All tableware is treated by boiling water after each meal. Clothing and bedding used by patients is disin-

fectured by steam before going to the laundry. Once each month rooms and wards occupied by patients undergo disinfection, the methods employed being sulphur fumigation, formaldehyd and washing with bichlorid, 1:1000, the last named being the most used. Rooms and wards occupied by patients are frequently recalcimined.

GENERAL TREATMENT: TENT LIFE.

The essential elements of treatment followed here are life in the open air, ample feeding and rest or graduated exercise. The patients live out of doors the entire day and sleep with doors and windows wide open; many during the spring, summer and autumn months are quartered in tents. After a brief period of such a life patients become very fond of it, and there is very little trouble in persuading them to stay out of doors almost the entire time. Ordinary colds are extremely rare when patients become accustomed to the open-air life, and we have not had a case of pneumonia since the station was opened, nor have I seen a case in Lincoln county, although I have had a fairly extensive general practice for over a year in resident Mexican and American families.

Cases quartered in tents do better than similar cases in wards—several in the past month have gained from

ing bag and a greater number take daily walks, and a few of the best cases are allowed to take moderate horse-back exercise. While the relative amount of rest and exercise necessary for various stages and classes of the disease is difficult to specify, in general I would say that the amount of exercise allowable should be in inverse ratio to the activity of the disease; each case should be considered alone, and rest or exercise prescribed with the same care we use in prescribing other remedies.

MEDICAL TREATMENT.

Medicinally we treat the disease symptomatically; for the cough, heroin or heroin and terpin hydrate, and codein are our most effective remedies, but comparatively few cases require cough remedies after the first few weeks. Dyspepsia, perhaps, gives us more trouble than any other one symptom; for this pancreatin and salol are often effective. Warburg's tincture and other bitter tonics sometime restore the appetite, and we find the various malt preparations very valuable tonics. Frequently we find that loss of appetite is caused by constipation or torpid liver, and in such cases sodium phosphate gives excellent results. A large number of remedies of reputed or established reputation have been tried with varying success, but, broadly speaking, our

Fig. 8—Old dining room, soon to be converted into a ward

10 to 20 pounds in weight, and even febrile and apparently hopeless cases do better in tents; they are more comfortable, have less fever and cough and better appetite. The tent dweller loses all fear of night air, and the mode of life is so popular that I have recently been obliged to make requisition for an additional number of tents.

REST AND EXERCISE.

Most tuberculous patients seem to be under the impression that they should take as much exercise as they can possibly stand, and. I must confess, before coming West I had much the same idea. but my experience at Fort Stanton convinces me that more patients are injured by too much exercise than by too little; we find it constantly necessary to restrain our patients and order rest when they think themselves able to indulge in all sorts of exercise.

Cases having fever and hemorrhages, of course, require absolute rest, and those in which the disease is actively progressive should take but little exercise, and that of the gentlest sort. For patients who are convalescent making decided progress toward recovery we recommend one canquet and quoits. some use the punch-

Fig. 9—Patient's bedroom in convalescent building

efforts have been to keep in normal condition all the functions of the body, promote and satisfy a healthy appetite. keep patients in the open air practically all the time and by watchful care see that they do not prejudice their chances of recovery by injudicious physical exercise or surreptitious over-indulgence in stimulants.

Whisky has its place in the treatment of tuberculosis, and we use it in something less than 10 per cent. of our cases; its excessive use is, of course, prejudicial, and we have had several cases which were previously doing well. but dated their decline from excessive drinking of smuggled whisky.

Hemorrhages are usually controlled by ordinary remedies, but whenever persistent or copious we have resorted to the use of Murphy's treatment—the injection of nitrogen into the pleural cavity. I have now under treatment two cases in which this treatment controlled what I am satisfied would have been fatal hemorrhages, and they are now both making very satisfactory progress toward recovery. In our experience this treatment seems to exert no beneficial influence on the lung lesions aside from the control of hemorrhage. but there has been

recurrence of hemorrhage in no case in which it was used.

Food is an element of treatment equally as important as air, and our aim is to supply patients all they can eat as often as they desire it. A diversified diet is prescribed, meat and fresh milk being served at all meals, and eggs for breakfast and supper; we also have a lunch of milk and crackers at 10 a. m. and raw eggs and milk in the afternoon are prescribed for patients requiring additional nourishment. We have had excellent results with tropon, one case on a diet of milk, raw eggs and tropon gained 14 pounds in a short time.

DURABILITY OF CURE.

The question is often asked: "If I become cured here will the cure be permanent and may I with safety return to my former home and occupation?" We have only been able to keep track of a few of our discharged cured patients, and in none of these has there been a return of the disease, but the data at present available are not sufficient to warrant giving a positive reply, either in the affirmative or negative to the question. I advise that apparently cured first stage cases remain in this or similar climate at least six months after disap-

He returned to his home in Washington, D. C., and about the middle of January wrote me that he had had a serious relapse, and asked to be again received as a patient. He was readmitted Jan. 28, 1901, and examined with more than ordinary care; there were physical signs of acute bronchitis, but the most careful microscopic examination failed to reveal bacilli; his sputum was then injected into the peritoneal cavities of two guinea-pigs, which were killed at the end of eight weeks and found to be in a perfectly healthy condition. This man recovered from his bronchitis in a short time and is now doing duty as night-watchman.

CASE 3.—The third case is that of a young man 21 years of age who was admitted, Aug. 28, 1901, in the first stage of the disease, tubercle bacilli being present in his sputum; he made rapid gain in weight; cough and expectoration ceased entirely by Jan. 1, 1902, and for more than three months he had absolutely no symptoms, and was about to be discharged from further treatment. A few days ago, on arising in the morning, he coughed once, expectorating a small portion of mucopurulent matter, which on microscopic examination was found to contain tubercle bacilli in considerable numbers well grouped. The bacilli had previously entirely disappeared from his sputum.

CASE 4.—The fourth case, in which there was extensive involvement of both lungs and larynx, with almost entire loss of

pearance of all symptoms, and second and third stage cases a year, but many of the latter would do better to reside permanently in a favorable climate. I cite the following cases as bearing on the point:

CASE 1.—W. D., aged 50 years, in the second stage of the disease, with consolidation of the upper lobe of the right lung, was admitted June 14, 1900, having had at that time the disease twenty months; bacilli were demonstrated in his sputum and there was mixed infection. He was discharged, apparently cured, Jan. 15, 1901, and employed as cart driver; his appearance was that of perfect health, and he remained well until June, 1901, when he had an attack of influenza; this disease ran its course, but the patient did not recover strength, and the cough continuing beyond the usual period led to re-examination of his sputum when the tubercle bacillus was again found. He was very ill for several months, and at one time it was thought he would die, but he is now almost well again. There is scarcely a possibility of reinfection in this case, but this seems rather to have been a breaking down of a partially or entirely encapsulated mass of tubercular deposit during the attack of influenza.

CASE 2.—A second case is more encouraging: W. K., aged 28 years, admitted Dec. 19, 1899, with consolidation of the right apex and the left upper lobe and a history of lung trouble extending over 11 years, was discharged apparently cured, Dec. 10, 1901, nearly a year after all symptoms had disappeared.

voice, patient extremely weak and much emaciated; was discharged after 15 months' treatment, and for the past year has been employed as wagon driver in the nearby town of Capitan, N. M. He has entirely recovered his voice, strength and usual weight, and remains well, so far as physical signs are concerned, and is strong and hearty.

The lessons and encouragement to be gained from these cases seem too obvious to require comment.

CONCLUSIONS.

1. Given a sufficient length of stay recovery may be expected in a very large percentage in first stage uncomplicated cases.
2. Recovery or arrest may be expected in a fair proportion of second and third stage cases and all the afebrile cases in which there remains sufficient sound lung tissue to support life, but we should exercise caution lest we be premature in pronouncing second and third stage cases cured.
3. Results in permanent febrile cases, especially those in which there is a wide range of daily temperature, are not better than in less favorable climates.
4. Hemorrhages seem less liable at this altitude than at the sea level.
5. Heredity plays an unimportant part in the causation of the disease.

control is directly demanded, some for whom the question is still *sub judice*, and some for whom this course appears contraindicated as follows:

1. Those for whom institutional care and control is demanded regardless of climate. Under this head may be properly grouped three fairly distinct classes.

(a) Those hopelessly ill and impoverished who may be permitted to enter segregation hospitals, apart from special sanatoria, where the last comforts of life may be administered without the slightest degree of danger to society, and where death may be robbed of a portion of its horrors through judicious nursing and medical care. Is it not apparent without discussion that the destitute and dying consumptive who is *persona non grata* in all municipal institutions for other classes of suffering humanity, and who is even denied admission in special sanatoria on account of the advanced nature of his disease, is entitled, however, from the commonwealth, on the grounds of humanitarian and scientific considerations, to some form of institutional provision.

(b) The consumptive poor who, in state sanatoria perhaps with industrial opportunities, can frequently be enabled to resume their duties and former positions in the community as wage earners. By this means protection accrues to society through the control thus offered of those unable in their ordinary environment to observe all sanitary precautions, and who necessarily tend in time with advancing infection to become a distinct element of danger. The consumptive thus receives from the state an energetic provision for the saving of life and health and the alleviation of suffering. His position in his family as a bread winner is materially improved, often preventing them from becoming a burden to society; and the state in turn from an economic standpoint adds to its resources by preserving one of its most valuable commodities, the earning power of labor. If it is incumbent on the state to provide for the poor who are not sick, but who have sunk to their present state on a line of little resistance through habits of shiftlessness, dissipation, or by reason of inherited perversion, and who may never hope to regain social cast or citizenship, how much more imperative is the demand to assist the consumptive poor who usually are not blameworthy for their misfortune, and for which society is to some extent responsible. The same reasoning may apply to our state prisons, reformatories and insane asylums, save for the single consideration of the public safety, and this appears a difference alone of degree.

(c) The ignorant or vicious, without especial reference to stage of disease, who refuse to conform to established rules and wilfully make themselves a public menace, for whom special detention institutions are appropriate.

This last-mentioned class of cases directly implies the necessity of inculcating a broader educational influence with its elevating and more submissive tendencies, through the wider, every-day diffusion of practical hygienic knowledge. Bearing in mind the two central thoughts toward which, as previously stated, all discussion of institutional treatment should be directed, and recognizing, as seems unavoidable, the utter inability of sanatorium construction alone to fully subserve such purposes, is not the thought sustained, although perhaps somewhat digressive, that certain corollary additions to sanatorium management are indicated to meet the requirements demanded by the enormous class of indigent consumptives. Such cases are out of all proportion to the capacity of any number of institutions, to say nothing of the pregnant fact that the true remedy

of the evil consists not alone in providing a temporary means of retreat for the victims of known conditions, but rather in conducting a definite system of defense. Such protection is to be accrued from the daily personal dissemination of practical truths in the very homes and workshops of the poor where exists the most "prolific habitat" of the disease. To this end and in connection with detention institutions is recommended the establishment of an out-patient dispensary service, with provision for the maintenance of an able corps of assistants for district work. These, by visiting the homes, studying the conditions and by power of kindly, personal contact, can not only relieve material conditions, but begin the actual propagation of knowledge. It is this educational influence within a community that reflects one of the chief benefits of all consumptive institutions. Those who have profited either at home or in sanatoria through the force of example, readily become in turn self-constituted apostles to spread broadcast the gospel to which they have become so much indebted.

It is reasonable to suppose that state and municipal sanatorium provision along the lines herewith suggested is not only obligatory from a high moral sense, but also practicable and economic as well.

CLASSIFICATION OF PATIENTS: 2 AND 3. SANATORIUM TREATMENT SUB JUDICE.

2. Those for whom institutional treatment *per se* is still *sub judice*.

(a) This division embraces almost entirely the large middle class with incipient infection and limited finances, for whom an inexpensive sojourn in a closed sanatorium offers some reasonable hope, if not definite assurance of improvement, without involving the financial sacrifice, the separation from family and friends, and the practice of rigid economy in a far country under strange conditions, and frequently with most unfavorable surroundings.

A tentative recourse to local sanatorium régime for such cases can not often result in any material injury, even to those subsequently sent away to seek climatic change. Their surroundings are certainly much superior to those previously experienced, and they are brought under the direct supervision of skilled medical advisers ready to recognize unfavorable changes or failure to respond satisfactorily to existing conditions. To these unfortunates the coming exigency may be earlier met than without an institution by a frank recital of the situation to the patient or friends with further climatic suggestions if within their practical means.

While the physician and philanthropic citizen of our open health resorts are ever ready to lend every aid to worthy impoverished cases of consumption regardless of length of residence therein or previous location, the fact remains that, generally speaking, it is no kindness to send such cases away from home. It can hardly be said that the consumptive with such limited resources profits materially from the hardships necessarily assumed by himself as well as imposed to some extent on others. Allusion is here made to those of his family who by dint of personal sacrifice manage to extract a mere pittance from their savings to contribute toward a portion of his support, and also to the resident employe in health resorts and his family in being forced to compete with the cheap labor of the unfortunate or desperate consumptive. While admittedly the invalid who is distressed financially is equally worthy with those more favored and is entitled to every sympathy and active consideration, this does not extend as a matter of real kind-

ness to sending him away without resources among strangers to battle against great odds in order to supply pressing necessities. With these the question is one to be reviewed with the patient in all its phases, and must be decided strictly on the special merits of the condition of the individual himself and is hardly subject to further generalization. Many such have less to lose and more to gain by residence in closed sanatoria. It must be insisted, however, that a certain proportion of such incipient cases without expectoration, without bacilli and without money, now frequently admitted to sanatoria, constitutes but a slight source of danger to the community, and with slight financial assistance in the beginning in an appropriate climate are not too ill to engage in some occupation, if necessary, with a reasonable assurance of improvement.

(b) Another class comprises those with considerably more advanced infection sufficient to render prognosis doubtful in any climate with perhaps a somewhat more comfortable financial status. With these the separation from family and relatives, with the necessarily prolonged absence, the knowledge of the grave possibilities, the physical discomforts and the mental anguish are frequently sufficient to cast the vote against the hardships of an extended journey and the struggling adaptation to radically new surroundings. Unfortunately, however, it is not to such a class that the sanatoria at present in existence extend a welcome. In all institutions with which I am familiar only the most incipient cases are admitted. To such an extent is this practiced, and naturally enough to be sure, that at a certain popular institution "patients are admitted from the list of those who have passed the necessary examination, not in the order in which they have applied, but according to their physical condition, the most favorable cases being admitted first." In view of the inability of such cases to gain admission to closed local sanatoria the only alternative short of despair is attempted climatic change. It is but fair to state that this procedure should not be resorted to without full appreciation on the part of the family of the utter uncertainties attending the change. Neither should it be undertaken without provision having been made to permit the subsequent elaboration of a sanatorium régime, or at least its approximate approach in a new climate where no admission blanks are required.

3. Cases for whom residence in local closed sanatoria are not unqualifiedly recommended.

In this class are embraced all with incipient or moderate infection who are not prohibited by financial or other cogent reasons from seeking climatic change.

In explanation of this somewhat surprising and perhaps arbitrary classification it should be borne in mind that the essence of this particular phase of the inquiry relates exclusively to the best possible provision to be made for such cases. An enormous class, who are intensely anxious to avail themselves of every rational opportunity to recover from their disease, appeal to their medical advisers for nothing less than that which offers the greatest and most reasonable assurance of ultimate arrest. Cases such as these, willing to enter the lists and engage in the prolonged struggle destined so frequently to be a trial to their patience and a test of their endurance, fortitude and bank account, with their own existence and the happiness of near ones as the issue, surely deserve such preparation and fortunate choice of battleground as will insure the greatest probability of final success. The situation is one fraught with tremendous responsibility. The obligation of the physician is not fulfilled by advising merely what is admittedly good,

but is satisfied only by urging only what is actually the very best for the individual case. It is not a question of the possibility or probability of securing arrest within a local institution, but rather whether such environment is, of itself, the method most likely to accomplish this result. The position of the physician is somewhat analogous to that assumed by the surgeon in considering the advisability of operation in appendicitis. It is admitted that the patient may recover in a given case without surgical interference, but insisted, notwithstanding, that his chances are better with immediate operation. The fact that invalids occasionally recover from incipient tuberculosis without climatic change is no more to be considered as an argument against the wisdom of its special application than is the recovery of a given patient with appendicitis without operation to be considered a reflection on its surgical utility.

Should not the physician in assuming to direct the destinies of his well-to-do-patients make a practical application of the condition to himself and advise in accordance with the course he would himself pursue under similar circumstances. Were such the case little doubt can exist as to the promptitude and certainty of action. The logic of climatic truths to be applied in this connection in appropriate health resorts consists in the more complete elaboration of the very principles on which depend the efficacy of sanatorium management, viz., an essentially out-of-door life. If the doctrine of out-door living means anything as directed toward the pulmonary invalid it means that the best results are to be obtained through its most complete fulfillment. It follows that the fullest conception of a proper method of open-air existence can be satisfactorily conducted only in those regions affording the maximum amount of sunshine with associated warmth and dryness together with favorable conditions of soil. If to these attributes be added moderate altitude and rarefaction there are exerted at once certain intrinsic influences distinctive of the locality, yet being in fact but the attainment of the higher results attempted in less favored regions along precisely the same lines. Reference is made to the continuous expansion of the contracted chest and the vesicle dilatation with increased pulmonary capacity through the unconscious efforts of lung gymnastics. In addition the increase in vigor of the heart contraction produces an acceleration of the blood flow and an equalization of the circulation diminishing the tendency to local pulmonary congestion. By virtue of these influences, together with the increase of hemoglobin and the number of red blood cells incident to the altitude, the desired changes in the appetite and nutrition are more readily secured. While it appears invidious in this connection to exploit ever so briefly the virtues of any particular climate, it is nevertheless opportune at a time of local sanatoria agitation with the prevailing tendency to repudiate the established facts of climatic influence to reassert the value of the conjoined effects of proper living together with an appropriate climate. As expressed in a previous paper: "If a suitable regimen without the favorable influence of climate is capable of producing a perceptible improvement in very incipient cases, how much greater and more enduring results and in how many greater number of cases, advanced though they be, may be obtained by precisely the same manner of life plus the beneficence of climate. If a system of regimen necessarily incomplete in moist, cloudy regions is good, a well-nigh perfect adherence to its principles in a land of perpetual sunshine, invigorating air, inspiring scenery and blue sky is certainly better."

Recognizing the comparative rarity with which consumption has originated for generations in the midst of certain climatic conditions, and the relative frequency of its development and rapidity of its progress in the absence of these essentials, does it not follow as a logical sequence that climate must irresistibly take its position as an important factor in subsequent efforts to secure arrest. Should we not expect invalids, other conditions of management being equal, to do far better under those climatic influences which have constantly sufficed to prevent the development of the disease than when subjected to the same treacherous conditions which have operated directly in favor of its spread and which will continue to be in force for all time? The same process of reasoning extended in its application to the more remote future of the consumptive, leads inevitably to the conclusion that the individual, once a consumptive and always a consumptive, possesses the inviolable right to be placed, if possible, in the midst of a new and more favorable environment. He is afforded the greatest degree of protection against renewed tubercular activity or reinfection and is offered at the same time facilities for industry and business enterprise with possibilities of advancement and fortune incident to a new country.

CLASSIFICATION OF PATIENTS: 4, THOSE NOT NEEDING SANATORIA.

4. The sanatorium management in appropriate climates as opposed to the so-called home treatment in health resorts.

It would seem that climatic conditions being the same the solution of this problem should be made strictly with reference to the relative degree of success possible to be attained in establishing and maintaining a perfected system of disciplinary régime under which is properly included outdoor living, rest and superalimentation. It is true that these three elements constitute the cardinal principles of treatment in any climate and are indispensable for the accomplishment of the best results. Were these the only essential factors involved in a question relating to the lives of unfortunates, but nevertheless human beings, the decision would be quickly made in favor of the superiority of the closed sanatorium régime in its fullest interpretation on some remote hill-top or isolated mountain side. The fact remains that the consumptive, by virtue of his inheritance, his numbers and his individuality, is entitled at least to the provisional consideration of certain other fundamental principles. In spite of his bodily infirmities he remains a human being, and is not to be rounded up in segregated herds and arbitrarily subjected to the same ultra-scientific principles applied to the lower animals, with the only criterion on which concerted action is based being the presence of a definite micro-organism. A problem so delicate can not always, though perhaps sometimes, be fairly adjusted by a summary recourse to its medical and strictly sociologic aspects. The logical deductions from precise scientific facts and their application to the practical problems of everyday life demands that true science in its broadest sense takes cognizance not only of the findings of the bacteriologist, the physiologist and the chemist, but also to some extent at least of the common-sense experience of the clinician who is brought into daily contact with conditions as they exist. Thus it is that while life in a closed sanatorium is perhaps more strictly in accordance with the principles of modern phthisio-therapeutic thought, nevertheless in its special everyday application it does not necessarily conform

to the judgment of the medical observer, who is brought face to face with the various conditions and is permitted to note the actual results.

This has long been pre-eminently an age of statistics and statistical observations have by no means been lacking to apparently demonstrate the value of the sanatorium treatment. Without commenting on the peculiar conditions which obtain in many instances in explanation of recorded results and in full appreciation of the manifold advantages of such régime, it is fair to state that the uniformly good results are to some extent due to the character of cases admitted and not invariably inherent to the institution itself. May it not properly be asked whether equal or in some instances better results could have been obtained by the same interested and able medical adviser outside his institution. By as much as it is not the sanatorium alone, but rather the attending physician that determines the influence for good, by just so far must it be remembered that it is not the disease to be solely considered, but the invalid himself. The question of success or failure depends frequently on his ability to adapt himself to unusual conditions, and frequently this strength of character is sadly lacking. The knowledge of this fact should preclude any arbitrary attempt to sink his personal preferences and individuality into a merger of consolidated consumptive interests. The sole claim of sanatorium advocates rests directly on the extent of supervision permitted with reference to details of life. If this is true, and likewise their contention that such institutions are primarily for early cases alone, it would hardly seem that the favored few cases of this incipient character without complications, actually require the degree of personal attention rendered several times a day in these institutions. If close daily supervision of early cases is not fully or invariably demanded for the real good of such cases, if living under the same roof is not actually required, what is to prevent the medical adviser from exercising a sufficient devoted direction for his patient if he so elects in suitable abodes conducted somewhat along the same lines as in well-regulated sanatoria in accordance with the same well-recognized principles but on a smaller scale, and sometimes more to the convenience, happiness, social welfare and material benefit of the invalids? The selection of a residence, as has been my custom for years, meeting all known requirements for the desired purpose as regards location, sunshine, porch room, with frequently outdoor sleeping accommodations, the wise grouping of a chosen few with reference to congeniality, temperamental peculiarities, tastes, stage of the disease and financial ability, the presence of a competent housekeeper, or, if need be, a nurse as well, and finally the continuous oversight of the always accessible medical attendant, must afford a combination sufficient to produce satisfying results. It seems unnecessary to more than mention the improved psychic effect of such an environment, which has indeed a potent influence with a portion of pulmonary invalids, in comparison with that resulting from the heterogeneous assemblage of consumptives in large, closed sanatoria. Is not the idea of a home and genuine home life the true ideal spirit to be fostered in such cases together with a certain judicious amount of medical supervision, this not being permitted to predominate offensively, but nevertheless in existence as a non-intrusive and often silent factor in the constant physical guidance of the temporary household. Inspired by this motive there has been erected on the outskirts of Denver, through the marvelous genius of its

There are various other drugs, none of which deserve serious consideration, as they are usually advertised by agents commercially interested in their purchase.

Another complication requiring special attention in the treatment of pulmonary tuberculosis is that of more or less chronic gastritis, and often dilatation of the stomach. In such instances all medicines should be discontinued and a careful analysis of the contents of the stomach should be made after a test breakfast. Where hypochlorhydria exists this should be corrected. In the majority of instances, however, the most desirable method of treatment is stomach lavage about three times a week, and, in cases where dilatation exists, this should be followed by Einhorn's electrode. We must remember that the necessary overfeeding of our patients will periodically give us more or less gastric disturbance, and that this condition must be removed before we can expect any good results in the way of hypernutrition.

THE BLOOD.

Some observers have stated that there is a condition of anemia which antedates the development of tuberculous infection. While not willing to assume, at the present time, that this assertion is not correct, I simply wish to state as a matter of record that, according to data compiled during the past year, forty-two cases showed that pure tuberculous disease itself, whatever its seat (Cabot), has no effect on the blood, that fluid being normal in every instance; second, that sixty cases would seem to show that the *Diplococcus lanceolatus*, associated with the tubercle bacillus, is the primary cause of the severe anemia; third, that twelve cases showed that, when we have a case of tuberculous diarrhea, it is the drain on the body albuminoids and not the tuberculosis which is the cause of the severe chloranemia met; fourth, that the slight rise in temperature we often get in pure tuberculosis has not the slightest effect on the hemoglobin; fifth, that the temperature we get in mixed infection drains the red corpuscles of their vitality and lowers their number; sixth, that in mixed infection, with cavity and moist râles, and secondary anemia with leucocytosis, seventy-five cases showed the polymorphonuclear cells increased at the expense of the leucocytes, the leucocytes being of the large variety. But when the moist râles disappear and the cavity dries up leucocytosis disappears. Seventh, the blood of pulmonary hemorrhage does not show any nucleated red cells.

Where anemia does exist it must certainly be corrected before we can expect good results from other treatment. Good diet, outdoor life, the intelligent administration of iron and arsenic combined will generally prove efficacious. Static electricity is a very powerful agent in improving nutrition when given in conjunction with one of the foregoing remedies.

Hydrotherapy is also a very powerful factor in placing the victim of incipient tuberculosis in a condition to overcome the disease. In all large cities, and in many small ones, there can be found hydrotherapeutic establishments where patients can be sent and treated two or three times a week.

THE LIGHT TREATMENT.

During the past few months the attention of the profession has been very strongly attracted toward the good results possible to obtain in the treatment of pulmonary tuberculosis by different light rays. We know how efficacious are the ordinary rays of the sun toward destroying the virility of the tubercle bacillus, and that six or seven hours' exposure will render innocuous the most virulent sputum. Beneficial results of light in

living and sleeping rooms are too well known to be mentioned here. It is generally conceded that patients living in sunless rooms will never—no matter how favorable their other symptoms—recover from tuberculosis. Light may be applied by the general practitioner in the simple form of sun rays to the bared chest; the patient selecting certain hours of the day, stripping to the waist and gradually tanning the chest as freely as the face. When possible, instead of using this mild form of light treatment, it is better to give them exposures to the rays of the arc light. Very beneficial results have been obtained with the arc light at my hands in cases of mixed infection and in some of empyema. Pus products very soon show a marked decrease.

The most powerful light rays at our command at the present time are very properly called the "x- or unknown rays." They are far more searching, their action is much more powerful and good results are obtained in a much shorter space of time in the treatment of carcinoma. With this treatment we are, to a large extent, groping in the dark. At present it is not a safe agent in the hands of the general practitioner unless he has taken a special course of training in the physics of the x-rays.

It is now a demonstrated fact that the x-rays are a specific form of treatment in external tuberculosis as well as carcinoma. In the writer's hands both external carcinomatous and tuberculous growths have been thoroughly inhibited. It is impossible to state at the present time whether the results obtained by different observers in this direction will be more permanent than surgical interference, but there is strong reason to believe that they will. The treatment of internal disease, whether of carcinomatous or tuberculous character, has not been as well demonstrated as that of the external variety, but from the present indications it is to be hoped that very many cases of both of these diseases can be radically cured. The question before the profession at the present time is whether the x-rays lose any of their power in passing from healthy tissue to diseased tissue; or whether sufficient force and penetration can be employed on internal diseases without destroying the intervening healthy tissue? If this can be accomplished we have no reason to doubt that in the x-rays we will shortly have our most potent agent in the treatment of pulmonary tuberculosis. Satisfactory results have been obtained in the treatment of internal carcinoma, and as the effect of the x-rays on external tuberculosis is so radical, reasoning from analogy, it should be as effective in internal tuberculosis as well as in carcinoma, provided the tuberculous process be sufficiently circumscribed or localized. In carcinomatous conditions of the uterus and in external tuberculosis or lupus, the writer has seen neuralgic pains disappear immediately, the secretion suppressed within a very short time, and the activity of the disease inhibited. Let us hope, therefore, that before long we shall be able to obtain as successful results in the treatment of internal tuberculosis. The technic of x-ray treatment should be carefully observed. The tube should be placed about 8 inches from the surface of the body and all areas not to be acted on should be protected by sheet lead and absorbent cotton soaked with water. The skin should not be too rapidly tanned or x-ray burned, and in treating the lungs it would be well to alternate the points of exposure. Vaseline can be rubbed on the surface at night. Exposures should be of ten to twenty minutes' duration and repeated three or four times a week. The mucous membranes are more tolerant of the x-rays than the skin. Possibly the x-rays

may have an inhibiting if not a resolvent effect on tuberculous infiltration or consolidation without cavities.

SURGICAL TREATMENT.

Surgical interference in pulmonary tuberculosis has not heretofore held out much hope. Tuberculous empyema, complicating pulmonary tuberculosis, should always be turned over to a surgeon for proper treatment. Tuberculous cavities lying near the surface or non-specific abscesses, when located near the base of the lung, are subjects for surgical interference. When these cavities are located in the upper lobes it is better to employ intratracheal antiseptic injections or creosote, or to inject these fluids directly into the cavity with a hypodermic needle through the chest walls.

Compression of the lung by nitrogen gas can be passed over in a few words with the following comment: It is applicable only when no pleuritic adhesions exist or where, if they do exist, they can be broken down with a legitimate amount of pressure.

SERUM TREATMENT.

Finally, the treatment of pulmonary tuberculosis by different sera must be referred to. After a number of years of trial this form of treatment is still in the experimental stage. In cases of mixed infection anti-streptococcic serum, in doses of 15 c.c., will act as a specific against streptococci, thereby reducing temperature and sepsis and greatly stimulating the patient's nutrition. Two or three injections are generally all that is required.

Antitubercle serum undoubtedly possesses, in selected cases where mixed infection is not marked, the power of stimulating nutrition and, by increased phagocytosis, aiding in the removal of the tuberculous deposit and temporarily, we know not for how long, increasing the resisting power or partially immunizing the patient.

SYMPOSIUM ON TUBERCULOSIS.

Two articles of this series have previously appeared in THE JOURNAL. They will be found in the issues of November 22 and 29. The remaining articles will be continued in succeeding issues as follows:

Recent Investigations Concerning the Relation of Human and Bovine Tuberculosis. D. E. Salmon, D.V.M., Washington, D. C.
The Intertransmissibility of Human and Bovine Tuberculosis: A Review of the Experimental Evidence. R. R. Dinwiddie, M.D., Fayetteville, Ark.

Discussion on the above seven articles.

Sanitary Measures for the Prevention of Tuberculosis in New York City, and Their Results. Herman M. Biggs, M.D., New York City.

Discussion.

THE MICROSCOPE IN THE DIAGNOSIS OF SCARLET FEVER.*

W. K. JAKES, M.D.

Professor of Chemical and Microscopical Diagnosis, College of Physicians and Surgeons; Director of the Laboratory, Chicago Health Department.
CHICAGO.

Since Dr. W. J. Class¹ called the attention of the medical profession to the causative germ of scarlet fever, I have been in a position to learn the value of the microscope in the early diagnosis of this disease.

In the year 1894 there was established at my residence by the Chicago Health Department a sub-laboratory for the examination of cultures from anginas. It was at first only intended to assist in the diagnosis of diph-

theria, but it was soon found that the culture gave more or less valuable evidence in almost every disease which attacks the respiratory tract. In differentiating influenza from other inflammations it is invaluable. The extensive use of the culture has demonstrated to me that the term pneumonia is a general one, and that there are several germs that are capable of causing a pneumonic condition in the lung tissue.

The term pneumonia is as indefinite as that of tonsillitis. While the lung tissue is so constructed that a certain train of clinical symptoms follows the invasion of any one of these germs, the prognosis and treatment largely depend on the nature of the invading germ. La grippe pneumonia, tubercular pneumonia or typhoid pneumonia represent distinct and characteristic conditions. Through the Health Department Laboratory I have been in touch with the various prevailing infections in my part of the city, and have examined yearly more than a thousand cultures.

Dr. Class made his announcement at the beginning of what has since proven to be the most extended epidemic of scarlet fever Chicago has ever known. During the previous four years I had become familiar with the nature of the inflammations caused by the *Staphylococcus albus*, and as soon as Dr. Class called my attention to the coccus he described, I found that it differed in many important respects from the *Staphylococcus albus*.

The Class coccus was at first limited to the cultures from those who were suffering from scarlet fever. I soon noticed that it was also found in the anginas of nurses or attendants who had come in contact with the disease. In those who were immune from previous attack of scarlet fever it was capable of causing only an angina.

Unless the bacteriologist is familiar with the Class coccus he would take it for a vigorous growth of the *Staphylococcus albus*, but a study of several cultures of the organism extending over some days will reveal its individual characteristics. These are so peculiar that it is difficult to place it in any class of bacteria. It is very sensitive to environment and is modified in form so it may appear as a diplococcus, a streptococcus or a strepto-bacillus, merging from one to the other in the same culture. Only by studying many cultures can one appreciate this variation in form. It also has a wide variation in size—from a point which can just be distinguished with an oil immersion twelfth to (in old cultures) a coccus a third the diameter of a red corpuscle.

The multiplication is by division and it multiplies in all of its varying sizes. Because of its minute form it can penetrate almost any tissue of the human body.

The shape, as usually seen, is round, with what appears to be a hole in the center. This is due to refraction or to staining qualities. As the germ increases in size a dividing line may be seen in the center. In the older cultures, where the coccus is large, on each side of this center line the cell substance stains in the shape of a crescent with the points toward the line. It is very susceptible to environment and is often seen to assume the streptococcus form or to become egg-shaped and sometimes almost a bacillus. These are a few of the important characteristics. A more extended description has been given by Drs. Class, Wynkoop and Jakes.

Before one is able to understand the value of microscopic evidence in the diagnosis of scarlet fever, one must appreciate that the scarlet fever germ is a pathogenic organism which requires a susceptible condition in the patient to permit its entrance into the blood and tissues, where it multiplies and produces the disease known as scarlet fever. Individual resistance and because one

1. Medical Inspector, Chicago Health Department.

such invasion produces a life immunity, causes the larger part of the race to be immune against this disease.

The presence of immunity is an important factor in weighing microscopic evidence. Children who have had scarlet fever may be exposed to the infection and an angina result. A culture from this angina might show the scarlet fever coccus present, but because of the immunity due to a previous attack scarlet fever would not follow.

Only a small per cent. of the human race is susceptible to the invasion of this germ, and when it is present, even in large numbers, scarlet fever will not result unless the required susceptibility is present. The following is an illustration: A case of scarlet fever had been diagnosed as rheumatism. The patient, when I first saw her, was scaling profusely; large patches of epidermis were peeling from all parts of her body. Her infant, of two and a half months, which had nursed all through the disease, escaped until three months after, when it began teething; it then became infected and suffered with a severe form of scarlet fever. This case was also observed by another physician.

Each pathogenic germ has its favorite tissue to invade. Certain individual characteristics of the germ, the position and function of certain tissues favor this entrance. Hence we have the distinct parasites of the alimentary canal; those of the mucous membrane, etc. While germs have their favorite entrance to the body, other tissues may become susceptible and be the seat of disease. The clinical symptoms in the different tissues may be entirely different.

This is illustrated in tuberculosis. While the pulmonary tissue is the one most invaded, a joint, a gland or other tissue may become susceptible while the lungs possess immunity.

The clinical symptoms not only depend on the nature of the germ, but also on the tissue invaded. The pneumococcus may be able to invade the cerebrospinal fluid and produce a disease entirely unlike its invasion of the respiratory tract. The Class coccus may infect wounds, cause anginas and, as I have seen in one case, be the causative germ in pneumonia; but it only causes scarlet fever when it finds a susceptible patient whose blood permits sufficient multiplication to produce the disease.

Therefore, when a malignant growth is found in a culture from an angina, it is evident that the patient has suitable conditions in the mouth for the multiplication of this germ. The history of exposure, the absence of a previous attack, the age of the child and the constitutional symptoms, all give important evidence when combined with the growth of the culture and indicate whether or not the germ will invade the blood and cause scarlet fever. Thus, the combination of clinical and microscopic evidence will often make a diagnosis possible before the appearance of the rash. During the past winter I have been able to warn many physicians from the culture alone that the patient would probably have scarlet fever.

The entrance of the infection is usually through the mucous membrane of the throat, though it may gain entrance through wounds and is especially dangerous when introduced through the genital tract during parturition. The blood is the agent which distributes germs throughout the body. After they enter the blood stream the safety of the individual depends on the ability of the fluids to prevent multiplication and the tissues to resist the effects of the irritating germs. While at times there is a selective action, as a rule the severity of the case and the intensity of the rash are in-

dicated and correspond to the rapidity with which the germs multiply in the culture.

The stay of the coccus in the blood of those who recover must be very short and the time to obtain it is just before or while the rash is appearing. The blood, possessing germicidal powers, is the first tissue to rid itself of the germs, and it also becomes an active agent in destroying them in the various tissues. The skin is highly vascular and its layers are continually moving toward the surface, where they pass off in scales.

The surface of the scarlet fever coccus possesses a gluey property which favors its collecting in the finer capillaries of the skin. Its irritating qualities soon cause congestion which cuts off the bacteria in the superficial layers of the skin from the destructive action of the blood. When desquamation ensues the scales are filled with the scarlet fever coccus.

Laboratory workers have found that one way to increase the malignancy of a germ is to infect an animal and when the resulting infection is at its highest to again obtain the germs. In scarlet fever the skin is filled with germs at the height of the infection, and these are distributed through the scaling epidermis to infect other individuals.

It was pointed out long ago that the blood is the fluid in which the infection of scarlet fever multiplies. In the Class coccus we have a germ capable of passing through the mucous membrane into the blood and out again through the skin. As before stated, the susceptibility of the blood is essential in the production of scarlet fever.

As the rapidity with which the germ multiplies in the culture is of such value in making a diagnosis, some method by which this may be observed should be used. The test tube from which germs are removed by a platinum wire is not suitable. The metal culture boxes used by the Chicago Health Department for the diagnosis of suspected diphtheria are much the best. These permit the pressing on the surface, after a few hours' incubation, of a sterile cover glass and when it is removed it contains on its surface an imprint of the bacteria on the culture medium. Then the smear may be fixed and stained. This method shows all of the bacteria present and makes it possible to estimate which germs have multiplied most rapidly. The presence of the Klebs-Loeffler bacilli is easily noted. This method is of especial value in diagnosing the mixed infections so often present in anginas.

During the early part of this epidemic the diagnosis of scarlet fever could be made from the culture with more certainty than later when the disease became widespread. The whole city seemed infected, and many children, as well as adults, who possessed slight susceptibility had anginas in which the Class coccus was the causative germ.

My four years' study of the Class diplococcus may be summed up as follows: If a child has never had scarlet fever and the clinical symptoms are present (such as characteristic angina, vomiting, delirium and high temperature) a rapidly-growing culture of the Class coccus from such a case determines the presence of scarlet fever, while its absence excludes the disease. In some cases the culture has decided the nature of the disease before the rash was observed, the patient isolated and others protected. In other cases where the rash was present but the clinical symptoms obscure, the absence of the Class coccus decided the case as not scarlet fever. In mixed infection, where germs of scarlet fever and diphtheria are both present, the microscope is of life-

saving importance, as the more prominent symptoms of scarlet fever may obscure those of diphtheria.

In the diagnosis of scarlet fever the fact that the clinical symptoms are so prominent and unmistakable should not blind the physician to the fact that the microscope will give most valuable evidence, both as to the malignancy and the associate infections.

4316 Greenwood Avenue.

DISCUSSION.

DR. SENECA EGBERT, Philadelphia—There used to be some hesitation in the East about accepting the diplococcus of Class as the cause of scarlet fever. I think that the evidence submitted to us in this paper should help to remove the doubt. Dr. Jaques shows that a hidden danger may lurk in unsuspected scarlatinal anginas. All these cases should be carefully looked after, not only in the interest of the patient but in that of others who might acquire the infection.

DR. H. O. MARCY, Boston—How are the germs isolated and developed? Can the diphtheria and scarlet fever germs be grown together? Are there any prophylactic means by which we may hope to modify scarlet fever?

DR. H. D. HOLTON, Brattleboro, Vt.—I should like to ask if the author can differentiate by the examination of the germs between röteln and scarlet fever.

DR. JAKUES—Yes; it is possible by means of the test to exclude röteln.

As you will observe, I have been very conservative in my paper. I recognize the fact that the profession has not accepted the Class coccus as the causative germ of scarlet fever. To me it is as clearly the cause as the Klebs-Loeffler is of diphtheria or the pneumococcus is of pneumonia. I have given you a record of my observations with the hope that others may be able to profit by them. I believe if they will study this germ as I have studied it, they, too, may be able to obtain the most valuable evidence from the cultures of scarlet fever anginas. In more than one hundred cases I have been enabled to diagnose scarlet fever from the culture before the appearance of the rash. I have faith that if others follow similar methods they also may be able to have like results.

The Class coccus is not pathogenic to many animals, and this increases the difficulty of producing a curative serum. It multiplies with great rapidity and I am inclined to think it destroys by its multiplication and resulting complications rather than by its toxin. We must have a toxin to produce an antitoxin, and I now believe that the greatest hope of controlling this disease is in a prophylactic stimulation of the exposed person's cells. As a rule one attack of scarlatina produces a life immunity. Each individual cell of the recovered individual possesses great power of resistance toward the scarlet fever germ, and this resistance does not become sufficiently lowered during the life of the individual to permit a second invasion of the germ. If in some way the resistance of a child's cells could be increased when it is exposed to the disease, there would be a temporary immunity. The Chicago Health Department has made some experiments along this line, but the results have not been definite enough to publish.

In reply to the matter of the blood infection, I will say: It seems incomprehensible that this germ should be the causative germ of scarlet fever and have escaped the observation of thousands of trained bacteriologists. I can only account for it in two ways: first, that it so nearly, in its early growth, resembles that most common germ, the *Staphylococcus albus*; and second, because of the attempt of bacteriologists to make every pathogenic germ comply with Koch's law. We are now breaking away from this, and we are certain that the *Bacillus typhosus* is the causative germ in typhoid fever, even if it does not comply with Koch's law. We are also appreciating that each pathogenic organism is a distinct living being with its distinct laws of development. Because of these distinct properties and characteristics, it is able to invade certain tissues. Our success in the control of these germs depends on a complete knowledge of each germ. Think for a moment of each of the well-known germs of disease and see how each differs in its

properties and methods of causing disease. Therefore, we must expect that the organism which is capable of causing scarlet fever will have its own distinct characteristics. I hope that when the exact position of the Class coccus in the bacterial flora is worked out, we will be able to find some weak spot in its life cycle or some method of increasing the defense against this scourge of childhood.

DR. S. A. KNORF, New York—I would like to ask whether the author of the paper has ever tried to verify his experiments with monkeys; if not, I would suggest that it should be done because of the valuable information that has been gained with these animals in regard to other serums. I would like to see the *modus operandi* described a little more in detail, and would also wish to inquire whether an examination of the blood would not be more satisfactory.

DR. JAKUES—We have no monkeys in Chicago we can employ in that way.

It is difficult to get the germ from the blood because of its germicidal action. It must be taken from a vein during the appearance of a rash and at once mixed with a large amount of bouillon. I have never been able to develop it from blood spread on the surface of culture media.

DR. KNORF—What culture medium is used? Has any plan been devised by which the physician can collect the germs himself, and send them to the board of health, as is done with diphtheria germs?

DR. JAKUES—Certainly. The culture medium is the same, and the suspected material can be sent in the same way, and the answer given by telephone if necessary, which seems to me a matter of considerable importance, as it lets the physician know at once whether he has got to deal with a case of scarlet fever or must look for indications of diphtheria.

DR. D. T. NELSON, Chicago—There is a thought in my mind which I may not be able to make clear, but I think it raises an important point, and I should like to state it. Vaccination is infection with a disease, the same, but a milder form of smallpox. Now, smallpox you have but once, as a rule. So also with yellow fever, you have it but once, and the same is true of other diseases. Now the point on which I desire enlightenment is this: Is scarlet fever a disease which we are to cure by antitoxins or prevent by vaccination—whatever that means, which I confess I do not know? Are we to use vaccination as we do in the case of smallpox, or antitoxin as we do in the case of diphtheria? And is yellow fever to be prevented in the individual like smallpox by a kind of vaccination, or like diphtheria, to be cured only when contracted by an antitoxin?

DR. JAKUES—As I have indicated, I think the *Diplococcus scarlatina* is a distinct organism and that it has its own methods of multiplying itself and acting on the body. Each of these different organisms has to be fought in a different way and by different methods. I do not yet feel justified in saying that we have hope of discovering an antitoxin for scarlet fever. I have seen it reported, however, that a European physician has succeeded in curing a patient by serum taken from another person who had recently recovered from scarlet fever. There would, of course, be manifest difficulties in taking serum from the human body apart from the danger of transmitting syphilis and other diseases. I merely mention the fact to show what is being done in an experimental way. I hope that some day we will find an animal that will produce a suitable serum.

A French observer, Bougald, claims to have discovered the germ. In regard to the experiments on the pigs, I may add that the toxin was injected into other animals, and that they all took the disease.

DR. BENJAMIN LEE, Philadelphia—Can two germs be found in the same individual?

DR. JAKUES—Yes, the germs of scarlet fever and diphtheria can frequently be found in the same person, and this renders it important that we should ascertain what germs are present. I believe that many deaths attributed to scarlet fever are really due to diphtheria.

DR. A. R. REYNOLDS, Chicago—The Chicago Department of Health hopes to carry these studies further. At present we have not the necessary funds, but as soon as we get them we

will go into the country and conduct the experiments. Our experiments in the city, as you have heard, were interfered with by the outbreak of scarlet fever in adjoining buildings. This made the results we obtained open to some question. I hope in future we will be able to report experiments conducted under more satisfactory surroundings.

Dr. MARCY—What age were the pigs?

Dr. JACQUES—About nine months.

THE TREATMENT OF FRACTURES OF THE LOWER END OF THE RADIUS.*

CARL BECK, M.D.

Professor of Surgery in the New York Post-Graduate Medical School and Hospital; Visiting Surgeon to St. Mark's Hospital and to the German Poliklinik; Consulting Surgeon to the Sheltering Guardian Society Orphan Asylum; Life Member of the German Surgical Society.

NEW YORK CITY.

The *modus operandi* of reduction in fracture of the lower radial end depends, as in all fractures, on the type of displacement. In the majority of cases the fragment is directed upward so that there is a dorsal prominence. The joint not being concerned in such cases, generally called typical Colles' fractures, the shape of the deformed wrist resembles that of a bayonet or a fork. The Roentgen rays have shown, however, that the upward displacement, as a rule, is associated with side-ward displacement, generally in the outward direction, causing radial inversion and consequently slight shortening of the radial axis. In such cases the clinical diagnosis is not difficult. The lower fragment pushes toward the dorsum, at which a prominence is seen, near the wrist, corresponding to a groove at the site of the upper end of the fragment. The upper (diaphyseal) fragment presses against the flexors, producing a prominence further upward. The greater the prominence, the shorter the radial axis. Crepitus is, even in these typical cases, often absent. In a small number of cases the direction of the displacement is found to be toward the ulna, even if the diaphysis is not kept in pronation.

There also are a number of cases observed by myself, as well as by others, where the lower fragment is turned backward around the transverse axis. Sometimes the sagittal axis of the lower fragment is turned around. The oblique type (triangular fragment like the fracture *en bec de flûte*), in which the joint surface is split, has never been recognized before the Roentgen era. Figure 1 shows the flat upper surface of the lower fragment slightly turned inward in a case of this type. The detachment of the posterior border of the joint surface is rarer. Roberts also observed forward displacement of the fragments.

By being upwardly dislodged the carpal end is brought into slight supination, while the diaphysis is in decided pronation. The epiphysis being in very close connection with the ulna, the latter is slightly pushed toward the ulna if the ligamentous connection between the radial fragment and the ulna remains intact. This phenomenon finds its conspicuous clinical expression in the lateral prominence of the styloid process of the ulna.

Wherever displacement demands reposition the assistance of one or two persons is desirable, who should make counter-extension while the surgeon replaces the displaced fragment. After the exact situation of the fragment is ascertained by the fluoroscope, the surgeon knows at once how to replace it on its former and normal position. This is done by making manipulations

either in the way of pressing the fragment sideward and turning it, or by putting the wrist at a proper angle, and thus correcting the abnormal direction. It is needless to say that upward displacement requires pressure from above downward, outward displacement pressure from within and inward displacement pressure from without. The triangular type (Fig. 1) generally requires downward and inward pressure.

The following method I found most useful in the majority of these cases: The hand of the patient is grasped as in a firm handshaking by the left hand of the surgeon, while the patient's thumb is held by the right hand of the surgeon in such manner that the thumb of the latter presses the fragment downward

Fig 1—Oblique triangular fracture. (*Articular fracture en bec de flûte*)

while the surgeon's index finger presses it inward at the same time. If the direction of displacement is toward the ulna the surgeon grasps the patient's hand, including the thumb, with his own right hand and pushes the fragment outward with his left thumb while he supports the flexor aspect with the rest of his hand. During these manipulations counter-extension must be exerted at the elbow. If it appears to be impossible to reduce the fragment in this manner, anesthesia must be employed. This manner is sometimes facilitated by placing a book or a piece of wood underneath the ulna at the edge of the table.

I have never failed to reduce the fragments in fractures of this type since the Roentgen rays have become such a reliable adviser. Even in impacted fractures I

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard.

could always disentangle the interlocked fragments. If there is a simultaneous injury of the lower end of the ulna showing displacement, special care must be taken to press the fragment in its normal place (Fig. 2). In multiple fractures, even in the much-dreaded Y-shaped variety, the articular arch of the radius may sometimes be restored by repeated efforts of reposition, controlled and corrected by the Roentgen rays. But if this proves to be impossible speedy osteotomy must be resorted to.

After reposition is accomplished a fixed dressing must be employed for the purpose of retaining the fragments in the proper position. This is not always easy. I find that no dressing accomplishes the purpose of retaining the fragments better than plaster of paris, since it adapts itself to the contours of the wrist in any desired

by well-padded splints. But no effort at reduction has been made. There is contraction of the fingers, which has not yielded to treatment yet.

If the direction of the displacement is slightly upward, or upward and outward, a plaster-of-paris dressing embracing the thumb is applied. I find that the

Fig 2—Displacement of ulnar end

shape or direction, and can be adapted to the individuality of each case

Before the Roentgen era the fear of ischemia and gangrene prevented me from using it immediately after the injury. Now, that the premises of ischemia are known to be wanting as soon as the pressure of displaced fragments is removed, such fear is uncalled for. So, while in former years I applied splints first and resorted to the plaster-of-paris dressing four to seven weeks afterwards, I now apply the plaster dressing immediately after reduction, resorting to the plaster-of-paris splint treatment a week or two later, as the case may require. If the protruding fragment is not reduced gangrene of the overlying tissues may be produced by any kind of dressing. Figures 3 and 4 show extensive gangrene at the dorsum as well as on the palm, which was caused

Fig. 3.—Pressure gangrene, caused by splints Dorsal aspect.

direction of the thumb influences that of the fragment to a great extent. The hand is moderately flexed at the same time. If gentle pressure of the index finger does not suffice to keep the fragment down, it must be pressed down by a signet or a wooden stick, around which the bandages are wound. After the splint

Fig 4—Pressure gangrene, caused by splints Palmar aspect

is fastened with a bandage the fluoroscope shows whether the fragment is in a desirable position. A dorso-palmar as well as a lateral examination must be made, because an antero-posterior view only shows whether the lateral displacement was reduced. The lateral examination also elicits whether there be any upward displacement.

Figure 5, for instance, illustrates an enormous degree of displacement in osteo-epiphyseal separation, followed by great functional disturbance. Dorso-palmar projection showed sideward displacement, but did by no means do justice to the real anatomic state, as it was found by lateral irradiation. The arch of the wrist is highly elevated, stretching the overlying tissues unduly. Four months having elapsed since the injury was sustained,

Fig 5—Considerable upward displacement in osteo-epiphyseal separation (Compare Fig 6)

the only remedy will consist in osteotomy. Figure 6 shows the shortening.

If the fluoroscope shows imperfect adaption the bandage must be removed and reposition done over again. Under such circumstances the fragments may be better retained if the thumb is pulled in an outward direction while the hand is shifted to the opposite side. The plaster-of-paris dressing applied in this position resembles the old pistol splint of Nélaton. Of course, the outward bending can be increased ad libitum. A sur-

geon must not lose patience if his efforts fail several times; by the fluoroscopic guidance he will at last surely find the proper angle, or, in other words, the most suitable position and shape of the dressing or splint for his individual case. One mistake often suggests the best mode of correction.

If the displaced fragment is directed to the ulna, in which case there is generally an outward bending of the ulna present, immobilization is kept up best by turning the hand inward. After a week the dressing must be removed, and if the edema has disappeared a plaster-of-paris splint, molded after the same principles, may be substituted, which can be taken off temporarily, so that massage treatment may be employed if necessary. The essential part of these splints is the encircling of the thumb, which guarantees absolute immobilization.

Fig 6—Upward displacement shown by Fig 5. Palmar prominence and shortening of forearm

In the case of a woman of 25 years the lower fragment was turned toward the ulna and also around the axis. It goes without saying that this extraordinary degree of displacement showed considerable deformity. Reposition was accomplished without anesthesia, the wrist being immobilized in superabduction. The skiagraph taken through the plaster-of-paris dressing showed that the abduction was overdone, wherefore another dressing was applied in moderate abduction. This position showed the fragment in better coaptation, but there was a tendency of the ulnar side of the fragment to project upward, partially filling up the interosseous space. Elastic pressure, recommended by me in the treatment of metacarpal as well as of metatarsal fracture, also proved to be useful in this case. A small piece of rubber drainage tube (the diameter of a small pencil) was placed alongside the interosseous space and fastened with a small strip of adhesive plaster. Now the skia-

graph showed perfect adaption. That it has spoken truthfully was evident from the absence of any reaction which should have been expected in view of the enormous degree of displacement and by the speedy and blameless recovery.

In the multiple T- or Y-shaped variety there are generally two diverging fragments, one being shifted toward the ulna and the other outwardly. By pressing the fragments asunder, so to say, the diaphysis is made to push itself forward so that it touches the scaphoid bone, the arm consequently being shortened.¹ Here the circular plaster-of-paris dressing in abduction is indicated. After that fragment, which is outwardly displaced, is pressed inward, a pad of adhesive plaster is placed above it. The fragment which is displaced toward the ulna must be shifted in the direction of the radius. To prevent slipping back, a rubber drainage tube is placed between it and the ulna at the dorsal aspect. By gentle pressure it is squeezed down in the

times impossibility—of perfect reposition of the splinters.

I confess freely that I often thought I had reduced a displaced fragment thoroughly because palpation seemed to give thorough satisfaction. But I was sometimes not a little surprised that the Roentgen plate showed me most impolitely how ill I had succeeded in my alleged reposition. In a former publication on the subject I have advised as a method of self-education to draw an anatomic sketch of one's silent diagnosis and then compare it with the skiagraph. Thus we learn on one hand that we can not always depend even on a highly cultivated palpatory talent, and on the other hand, we are taught to improve the power of judgment by comparing our sketch with the lifelike picture as it is given to us by the Roentgen rays. There is no doubt that the same good results can be obtained by other methods of immobilization, provided they are preceded by proper reposition controlled by the Roentgen light.

The main principles of treatment are the same for the other types of fracture of the lower end of the radius. There are, however, several modifications according to their different anatomy. If in chondro-epiphyseal separation no sideward displacement exists, the antero-posterior exposure shows nothing abnormal, while a side view may disclose considerable upward displacement. This is best treated by gentle downward pressure without using counter-extension and the application of a plaster-of-paris dressing in extension. If a lateral view shows any sideward displacement under the dressing, a pad of adhesive plaster is attached to the skin above the lower fragment and the dressing reapplied.

This is characteristically illustrated by Figure 7, which represents a case of separation of the radius associated with fracture of the lower end of the ulna. While the deviation of the ulnar fragments appear conspicuously, there is only a very slight inversion of the radial epiphysis noticeable. But it would indicate by no means that so enormous a degree of upward displacement would exist, as Figure 8 shows by lateral exposure.

In osteo-epiphyseal separation, where the fracture line is not limited to the epiphyseal cartilage, but extends to the diaphysis, a greater tendency to displacement is observed. The principles of treatment are the same as that of the complete fracture described above, since the tendencies to the various forms of displacement are the same.

Fracture of the lower end of the radius associated with fracture of the styloid process of the ulna is rather frequent. My own statistics show that the styloid process is involved in 30 per cent. of the cases. This injury was discovered long before Roentgen by Nélaton and Velpeau, and studied especially in this country by Pilcher, Roberts, Freeman, Corson, Thomas, Don, Haughton and Colton. I recommend the circular plaster-of-paris dressing in moderate abduction for this type. Sometimes it is possible to grasp the process and push it back into its proper place. This is easy, provided the process is displaced outward, but in case of inward displacement reposition is much more difficult. I found it useful to press this fragment outward by pushing the dull end of a pencil between the process and the radius and keeping it there until the dressing is completed, the bandages being wound around the pencil. A small piece of rubber tube being also placed there.

A small amount of pressure often suffices to push the fragment into position, while after the elapse of weeks the inversion of the process may cause intense pain on

Fig 7.—Chondro-epiphyseal separation of lower end of radius associated with oblique fracture of lower end of ulna

interosseous space and kept *in situ* by strips of narrow adhesive plaster, which do not entirely surround the arm. Since this type is intra-articular it is understood that there is always a well-marked extravasation, which may even extend over the sheaths of the tendons so that palpation is rendered difficult. There early massage is best employed to remove the extravasation

Among all the different varieties of fractures of the lower end of the radius these intra-articular injuries are most serious. It is only the continuous control by the aid of the Roentgen rays of the proper position of the fragments which will promise a fair result. In the case of considerable comminution a perfect restitution in integrum can not be promised. A skiagraph taken at the earliest possible moment is a valuable document for the surgeon, since it proves the great difficulty—some-

¹ See Fractures of the Carpal End of the Radius, etc. *Annals of Surgery*, August, 1901.

any effort of bending the wrist, so that removal by chisel may have to be considered.

Fracture of the lower end of the radius associated with fissure of the neck of the ulna is treated after the same principles as the complete fracture of the lower end of the radius. This applies also to fractures without displacement. But if there be displacement—generally outward bending of the fragment sometimes in spiral shape—after reposition a plaster-of-paris splint in moderate abduction is applied. A pad of adhesive plaster is also placed at the outer aspect of the ulna.

Fig. 8—Chondro epiphyseal separation of radius, associated with fracture of lower end of ulna in lateral projection case, illustrated by Fig. 7

Should there be any inversion a small rubber drain must be pressed in the interosseous space.

Another co-injury, the transverse fracture of the scaphoid bone, deserves thorough attention. Fortunately, as a rule, but little or no displacement is present, but the character of the injury being intra-articular it is appreciated that there is considerable intra-articular effusion, which is largely responsible for the great tendency to adhesion formation in these cases. The treatment is practically the same as that for the simple fracture described above, with the difference that motion must begin early. It is therefore advisable to re-

move the circular dressing somewhat earlier than in the other types and to substitute a plaster-of-paris splint of the same shape. This splint may be taken off temporarily every day so that gentle massage can be commenced.

Fracture of the little bone portions (chips), generally of the extra-articular type, are often confounded with contusion or distortion. In such cases massage treatment is manifestly inappropriate; the treatment should be carried on after the principle of the treatment of fractures, viz., immobilization. This should be kept up for at least the first week after the injury and after the little fragments are redressed. Such chips are sometimes not larger than the head of a pin, and if they are separated from the dorsal or palmar surface of the radius they may not be at all conspicuous on the

Fig. 9—Fracture of lower end of radius, followed by overlapping of fragment and palmar dislocation of ulnar end (Compare skiagraph 10)

skiagraphic plate, while a lateral exposure will show them.

If the massage treatment so commendable in contusion is used in these cases it is not surprising that the patient becomes rebellious. It is, indeed, not at all indifferent whether a simple bloody effusion or keen-edged bone fragments are kneaded.

If the principles of immediate reduction are adhered to, the "gibbous wrist" will cease to be counted among the inevitable inventory of surgical clinics. Still, I am afraid, this is still a pious wish as long as there are surgeons who imagine that by virtue of their own especially developed palpatory talent they can judge the details of any fracture without the aid of the Roentgen rays. Some are willing to use them in "obscure" cases, but they do not realize that the cases which they regard as "non-obscure" would appear in a different light when

skiagraphed. In other words, what they regard to be a simple fracture turns out to be a complicated condition. The paradox may be justified here, that if they would see this complicated condition or the fracture type in its proper light, it might appear obscure to them.

Up to the present the question of correcting the deformities will have to be considered. Two to three weeks after the injury correction is possible by simple refracture. After the lapse of four to five weeks the only remedy consists in osteotomy in the fracture line. Aged persons suffering from deformity of this kind are exempted. If they suffer while motion is made, immobilization is best kept up with a moss bracelet until ankylosis of the wrist has taken place. Sometimes a small wedge must be excised from the ulna in order to permit of perfect reposition. Such operations must be performed under the strictest aseptic precautions—tearing of the wound edges must be avoided and the

and associated with palmar dislocation of the ulna. The protrusion at the flexor aspect corresponds to the projection of the diaphyseal end, while the dorsal prominence indicated the riding of the epiphysis. Figure 10 also shows the forward dislocation of the ulna, the extent of which is proportional to the amount of yielding on the part of the epiphyseal fragment. Consequently the arm was shortened. Skiagraph 11, taken through the plaster-of-paris dressing two days after osteotomy, shows the trimmed radial fragments in appo-

Fig 10—Skiagraph of hand, illustrated by Fig. 9

Fig 11—Skiagraph after operation showing trimmed radial fragments in apposition and the dislocated ulnar portion resected

wound itself should come in contact with the hands of the surgeon as little as possible, since all the work can be done with well-sterilized instruments. If the Roentgen rays show the efforts of early reposition to be unsuccessful under anesthesia, it is much wiser to expose the fragments by open incision at once, than to wait until the tissues around the area of faulty union degenerate. As soon as the bloody effusion is absorbed, the operation should be performed. Isolated bone splinters, the periosteum of which shows no more coherence, must be removed. If the fragments can not be brought into apposition by simple reduction, then the ends must be trimmed properly with wire, saw or chisel, and either indented or wired.²

Figure 9 shows the fracture of the lower end of the radius followed by overlapping of the lower fragment

sition and the dislocated portion of the ulna resected. Consequently the extremity became an inch shorter.

Diagnosis of Infantile Scurvy.—The differentiation of this condition from rheumatism, rickets, purpura and syphilis rests largely on the following points. Absence of fever. Early, constant pain, first in legs, then in back and arms, increased on motion—child lies with head flexed and rigid. Swelling at lower end of diaphysis of femur, very tender to touch, but neither red nor hot. Later stomatitis, bleeding from gums, nose, bowels, etc. The pathology consists in the anemia and the superiosteal and other hemorrhages. Rheumatism, which is rare under two years, is accompanied by fever and sometimes a red, hot swelling of the joints. Rickets is manifested by chronic painless swelling of the epiphyses and the presence of a rosary and head deformities. According to Pierson in *Progressive Medicine*

SARCOMATOSIS CUTIS.*

DAVID LIEBERTHAL, M.D.

Professor of Skin and Venereal Diseases, Illinois Medical College;
Attending Dermatologist Michael Reese Hospital and United
Hebrew Charities' Dispensaries.

CHICAGO.

It would far exceed the time allotted should we attempt to consider the class of true sarcomata occurring within the skin, or all those forms belonging to the class of sarcoid tumors, as mycosis fungoids, lymphodermia perniciosa and leucemia cutis. We will limit ourselves to the discussion of the idiopathic multiple pigmentary or hemorrhagic sarcoma (Kaposi) and the so-called sarcomatosis cutis (Kaposi) and their relation to each other, after citing cases of the first type from our own observation, which, differing somewhat from the usual type, offers some interesting points which tend to show that in the two affections we probably have to deal with an identical process.

A. IDIOPATHIC MULTIPLE HEMORRHAGIC SARCOMA.

CASE 1.—C. L., German, 40 years old, married, has three healthy children. His parents died well advanced in years from causes unknown to him. He never suffered from any illness nor had venereal disease. His present affliction dates from the summer of 1896, when he bruised his left leg on stepping off a street car. Soon afterward his feet began to swell and to become very painful; after a month or two there appeared dark spots and lumps on his feet. In the course of time these increased in number and spread up the legs, while spots developed on the arms and lastly in the groins and armpits. Pain in the feet continued for about two years, especially when he attempted to stand up, so that he was confined to bed, and after that time it subsided so as to be felt in cold weather and then in the lumps only. Some of these lumps disappeared, while others developed.

Examination.—I saw the patient first in October, 1899. He was tall and strong. The mucous membranes were well injected, the nervous and vascular systems, the various internal organs, the blood and the urine were normal, the integument was affected on the extremities only, the feet and limbs were thickened nearly up to the knees, the toes were broadened and clumsy and at the interdigital folds were densely arranged filamentous, horny outgrowths, and on the dorsum of the toes, pea to bean-sized, bluish-red, smooth and moderately firm nodules. On the inner side of the sole of the right foot were three plaques of the size of a quarter, arranged behind each other. The middle one was slightly raised and of a bright red color, which disappeared on pressure. It was beset with horny, thorn-like excrescences. The two others were of a dirty grayish-brown color and were saucer-shaped, smooth, hard and horn-like. Around the malleoli were similar ones. On the dorsa of the feet and over the tibiae were various round or oval nodules and nodes from the size of a pea to that of a nickel, some bluish red, firm, smooth and round, and others dark blue, soft and compressible, also dark brown, slightly depressed spots and blue ones level with the skin. On the outer aspect of the right tibia in its upper half was a group of about forty dark-bluish pea to bean-sized nodules closely arranged, and bearing on their surface lamellous, easily removable scales. The nodules were compressible. There were two groups of nodules of precisely the same character on the inner aspect of the left tibia. On the inner aspects of the thighs and in the axillae were bluish-red streak-like spots arranged parallel to Poupart's ligament and to the axillary arch respectively. They were perfectly smooth, not elevated, but the skin beneath was densely infiltrated and scarcely movable above the subcutis. This infiltration extended throughout the affected area and beyond the spots. On the right external epicondyle of the humerus was a bluish-red spot of the size of a dime, smooth, not elevated nor the skin beneath infiltrated and its color did

not change on pressure. There was a spot of the same nature on the ulnar side of the left forearm.

Subsequent History.—The patient was soon lost sight of until January, 1902, when he reported that he had suffered from phlegmon on the left leg in the fall of 1899, and from erysipelas of the face in the spring of 1900. Of the lumps some had disappeared without leaving any trace, while new ones had developed. His health during all this time had continued good. The examination of the patient resulted in the same favorable general findings as at the first presentation, but the local symptoms of the skin had somewhat changed. The pictures, which I show you were taken at this time. The spots on the arms had increased in size, were darker and slightly elevated, but still movable with the skin. There was also found one red-blue spot of the size of a bean above the one previously described on the epicondyle. It was not infiltrated.

The thickened feet and legs presented the following appearance: Of the three discs on the inner side of the right sole, the middle one lacked the spinous processes in its periphery and was dirty yellowish brown, cornified and of saucer-like appearance, like the other two.

The plaques on the outer aspect of the right tibia which consisted, at the previous inspection, of numerous blue compress-

Fig 1 — Case 1.

sible nodules now present a brown and hardened area, flattened in the center, bearing a horny knob-like outgrowth and lamellous yellow-brown scales. The two plaques on the inner aspect of the left tibia had changed in their centers to corneous cauliflower-like formations with dirty yellowish scales on their surface. In the periphery of these plaques are two zones, the inner consisting partly of flat, hard nodules and partly of compressible tumors; the outer, of depressed pinkish skin surrounded by a dark brown line level with the surrounding skin. Besides there were found over the tibiae brown atrophic spots, flat and dense nodules and compressible ones, and also areas of the extent of a dime to a nickel of normally appearing skin, but which on touch revealed dense infiltration.

Over the posterior aspects of the femurs were a number of brown, irregularly outlined, smooth, non-elevated spots of the size of a bean to a half dollar, the skin beneath some of these and somewhat beyond being densely infiltrated. Below the right scapula is a reddish-blue spot of bean size, the last one to appear until January, 1902.

In the groins and in the axillae the streak-like spots became transformed into chocolate-brown, flat, firm nodules of the size and shape of a bean; with the underlying infiltration remaining.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. W. T. Corlett, L. Duncan Bulkley and W. L. Baum.

About May 10 of this year the right sole became more swollen and very painful. I saw him a week later and discerned on the diffusely swollen and bluish sole in the metatarsal region five violet nodules from the size of a pin-head to a pea, very painful on pressure, not raised, but distinctly palpable as spherical bodies. During the past year he had felt pain in the older lesions during cold weather only.

Microscopic Examination.—A bean-sized, moderately flat nodule was excised from the leg for histologic examination, the wound healing promptly. Histologic findings as follows: Stratum corneum, lucidum and granulosum well developed, stratum Malpighii somewhat narrowed. The papillary layer is obliterated, especially in the central part of the nodule. The corium contains an abundance of coarse, fibrous connective tissue and within this thin and coarse bundle-like masses of medium-sized or small fusiform cells, especially in the upper strata. These bundles cross each other in various directions.

On the other hand, there are found numerous aggregations of the same cells with scanty fibrous tissue, and more so in the deeper strata. Throughout the corium are numerous lymph-clefts.

Of the blood vessels, which are very numerous within the cell accumulations, some show thickened walls, which thicken-

urination and frequent and painful evacuation of his bladder. This condition became more aggravated until I first saw him in August, 1898.

Examination.—He was short, very emaciated and of sallow complexion, the mucous membranes pale, the lungs slightly emphysematous, the heart hypertrophic, the spleen normal, the prostate gland hypertrophied. There was retention of urine, chronic interstitial nephritis, sclerotic arteries and slightly elevated temperature. The blood showed hemoglobin 65 per cent., reds normal, whites slightly increased in number. The integument was normal except on the penis and lower extremities. On the skin of the under surface of the penis, just behind the glans, was a bean-sized, bluish-red, roundly elevated, firm nodule, movable with the skin and not painful. On the legs, and especially numerous over the tibiae, were nodules and tumors of sizes from a pea to that of a hazelnut, bluish or brownish, more prominent or flat, solitary and in groups, some soft and compressible with scales on their surface and others firm, while between these were blue and brown spots of various sizes. These were not elevated, but the skin beneath was infiltrated. Some of the brown spots were atrophic.

On the dorsa of the enlarged and clumsy feet were flat, dense, brown nodules of the size of a split pea to a bean. The inter-

Fig. 2.—Case 2. Smaller nodule.

Fig. 3.—Case 2. Larger nodule.

ing is partly due to infiltration of the adventitia to which frequently are attached the streaks of cells and partly to a swelling and proliferation of the endothelium, while other blood vessels have a thinner wall looking as if ruptured. Some are densely filled with red corpuscles which may also be seen extravascularly.

Large masses of a yellowish-brown pigment are seen among the tissues, especially within the cell accumulations throughout the corium, besides pigment granules intra- and extra-cellularly, all this pigment giving the test of hemosiderin. Elastic fibers stained with Weigert's fuchsin-resorcin were found to be normal throughout the sections. Round cells are found here and there in small numbers intermingled with the others, while they are quite numerous around the sudoriferous and sebaceous glands and follicle sheets.

CASE 2.—H. G. Nothing in his family history has any bearing on his skin affections. He had no venereal disease. Ten years before I saw him his feet swelled and became painful, especially when walking. The swelling subsided to a certain degree, but after a time there appeared dark lumps on his feet and gradually ascending also on the legs, and at last one came on the penis. From time to time certain ones disappeared and others occurred. These lumps were painful on pressure. He complained of nothing else until five years after the skin first became affected, when he experienced difficulty in

digital folds of the toes were densely beset with rod-like, horny outgrowths like a brush. The inner side of the soles is the seat of dirty yellowish flat tumors, hard and cornified, elevated two lines above the level of the skin, with depressed center and smooth surface and of the size of a nickel to a quarter.

There was a similar one, bean-sized, anterior to the right internal malleolus and two, of the size of a quarter, below the left outer malleolus. There was no enlargement of the lymphatic glands. The patient died from uremia two months after I first saw him.

Microscopic Examination.—Two nodules from the leg, one pea-sized, of recent development and one bean-sized, of quite long standing, both moderately firm, were excised and prepared for examination.

1. In the sections of the smaller nodule: Stratum corneum slightly thickened, stratum granulosum narrow, as is also the stratum Malpighii. The papillary layer has vanished, the subpapillary layer contains wide lymph spaces, as does also the reticular layer of the corium. Throughout the corium, between sclerotic or normal connective tissue, there are round cells intermingled with sparse fusiform ones, arranged mostly in irregular streaks, and here and there in irregular aggregations. Around the glands is abundant round-cell infiltration. In many places the cell bundles are attached to the infiltrated adventitia of blood vessels. These are partly thickened, partly dilated.

There are no hemorrhages nor are there found masses of pigment.

2. Sections of the larger nodule show nearly the same conditions as those of the smaller, but besides there are found blood vessels with very thin walls, and densely packed with red corpuscles. Other free ones are found outside the vessels. There are also numerous masses of yellow-brown pigment and intra- and extra-cellular pigment granules. The cells, of which the round predominate, were arranged in a similar manner to those of 1.

COMPARISON OF CASES.

Comparing the anatomic findings in the two cases we observe in the first a prevalence of spindle cells, in the second of round cells. Both have a hazy, coarse, granular nucleus and a narrow zone of protoplasm. In the upper strata of the corium, in both cases, the bundle-like arrangement of the cells is more pronounced. While we find in the first case blood vessels with very thin walls and in places appearing as if ruptured, and numerous masses of pigment, and the same two conditions in the older nodule of the second case, these are wanting in the sections of the small recent nodule of the second case. In neither case was exulceration of the nodules observed.

Considering now the clinical as well as the microscopical findings of both cases, the diagnosis of *sarcoma multiplex hemorrhagicum idiopathicum* is justified.

OPINIONS OF WRITERS.

Since Kaposi¹ first reported these cases and applied to them the name *sarcoma pigmentosum*, the literature of the subject has increased considerably. A very animated discussion arose in regard to the name, inasmuch as this affection in some respects does not correspond to the requirements of a true sarcoma, that is to say, the tumors have a limited growth and may heal spontaneously.

On account of these and from differences afforded by a study of the histologic findings, Kundrat and Paltauf were of the opinion that these cases should be accredited to the group granuloma, which view is shared by other observers. Sellei² goes even so far as to propose for them the name *granuloma multiplex hemorrhagicum*. As if to do justice to both sides of the controversy Kaposi subsequently classed his pigmentary or hemorrhagic sarcoma in the group of sarcoid tumors.

The etiology of this disease is unknown. As early as 1882 de Amicis³ expressed the opinion that an infectious agent might play a rôle in the development of these cases. Other authors inclined to the same view, but hitherto no proof has been afforded by bacteriologic examination of the diseased areas or by inoculation. Another suggestion as to the etiology has been offered by Campana in his discourse,¹¹ in which he records a case showing neoplastic infiltration of the peripheral nerves in diseased areas, and therefrom drew the conclusion that the changes in the skin are trophic disturbances.

Semenow⁴ arrived at the same conclusion from the findings in one of his cases. There was accumulation of pigment in the spinal ganglia, swelling of the nuclei in the neuroglia and proliferation of the perineurium of peripheral nerves. He assumed to be supported in his view by the symmetrical arrangement of the lesions and the severe pain frequently occurring within them. However, it is well to question this theory on the ground that the skin is affected by the same cause and at the same time as the nervous system, or the latter is affected secondarily.

It seems plausible that this process represents a slowly growing sarcoma which may change secondarily and be-

come malignant and that the question of its etiology will not be solved before that of typical sarcoma becomes known. To speak with Perrin:¹⁰ "We are scarcely in the beginning of our knowledge of this affection." Therefore, we should rather accept the interpretation and the name which the genial diagnostician, Kaposi, has offered and so splendidly defended⁵ (1894), and not welcome other names or explanations unless they can be better substantiated.

This affection occurs mostly in males over forty years of age, but has been observed in a patient as young as five years by de Amicis.⁶ The diagnosis of idiopathic multiple hemorrhagic sarcoma offers as slight difficulty as its differentiation from other similar affections. The prognosis is unfavorable, although the administration of arsenic improves some cases temporarily, while there are even cases on record⁶ where permanent cure has been effected by the hypodermic administration of arsenic. It is of interest just here to refer to a case of Semenow's,⁴ in which an erysipelas migrans caused its cure.

B. SO-CALLED "SARCOMATOSIS CUTIS."

Let us now consider Kaposi's so-called *sarcomatosis cutis*. Kaposi describes it as follows: "On the trunk

Fig. 4.—Case 1.

and extremities there appear numerous bluish, flat or more prominent spots, on the palpation of which there are felt in the depth of the skin firm, elastic, flat roundish plaques, not sharply defined. Besides these, firm plaques are felt over which the skin is neither protruding nor discolored. In one case the plaques were painful; in another on pressure only, and in a third case there were found bluish-red prominent, smooth and firm nodules of sizes from a pea to a hazelnut. besides larger flat plaques with central depression. There were no enlarged lymph glands, nor any alteration in the blood. These cases are curable by arsenic."

The histologic findings are, in Paltauf's opinion, somewhat similar to round-celled sarcoma. Cases of this type were further recorded by Joseph,⁷ Spiegler,⁸ Tandler⁹ and others, but their number remains in the minority in comparison with the numerous recorded cases of hemorrhagic sarcoma.

The histology of different cases differs somewhat, although in most of them similar conditions are encount-

ered, as in the hemorrhagic variety. The horny layer is broadened, the stratum Malpighii nearly normal, the papillary in some places vanished. The subpapillary layer shows sclerotic connective tissue and numerous wide lymph clefts. In the deeper strata of the corium, the real seat of the affection, between scanty, or in places sclerotic, tissue bundles there are embedded irregular masses of round cells (in Joseph's case fusiform cells arranged in rows, infiltration-like), or such cells arranged in bundles or streak-like.

Within the areas of cell accumulation are wide lymph clefts and numerous blood vessels, the endothelium of some of these latter swollen and in proliferation. The elastic fibers are preserved throughout.

COMPARISON OF TYPES A. AND B.

Although he insists upon strict division between the hemorrhagic sarcoma and the so-called sarcomatosis cutis, Kaposi admits that there might be transitional forms between the two, as between all other forms

Fig. 5.—Case 1.

classified by him as sarcoid tumors. But we may go further and assume that this division can not be strict, but that both forms are the same process, with some modifications.

This view is supported by a study of our own cases. The character and arrangement of cells are in both types nearly the same. While it is assumed that the cells are arranged more in irregularly grouped masses throughout the whole corium in the hemorrhagic, and more especially in the deeper strata, and band-like in the form sarcomatosis cutis, yet we really find cases of hemorrhagic sarcoma, as our second one, where the upper part of the corium is only slightly infiltrated. In both of our cases the band- or streak-like arrangement of the cells is prevalent throughout. It is further claimed (Joseph l.c.) that the elastic fibers are wanting throughout the hemorrhagic node, while they are preserved in that of sarcomatosis. The fact is that they are unaltered in hemorrhagic cases, too, as is shown in our first case. Let us inquire in regard to the hemorrhages and

masses of pigment. We should find them in all cases of hemorrhagic sarcoma, but not in the other form. As above recorded, there were found no strong indications of such in the more recent and small nodule of our second case, while the older and larger nodule showed an abundance of them. From this we may infer that the hemorrhages and pigmentation are of secondary occurrence. The papillae are in a similar condition in the two forms, and the same is true of the lymph spaces. In our second case the latter were numerous throughout the sections; in the first they were found in the deeper strata of the corium only.

There is as much similarity in the clinical conditions as there is in the histologic. Concerning the clinical symptoms, we may state that in our first case there were found bluish-red spots in non-infiltrated skin, and bluish-red, rounded and firm, flat, or prominent nodules, as well as compressible ones, solitary or grouped, typical of the hemorrhagic form.

On the other hand, there were found characteristics of sarcomatosis cutis, such as bluish or brownish spots on densely infiltrated bases, as those in the axillae and inner and posterior aspects of the thighs, which infiltration reached into the subcutis and extended beyond the spots in the periphery, also irregular and dense infiltrated areas over which the skin looked perfectly normal.

Blood and lymphatic glands are found to be normal in both varieties. In the hemorrhagic form the skin becomes affected first on the distal ends of the extremities, but there are cases on record where another region took the lead. In the sarcomatosis cutis the skin lesions occur irregularly on the body, but they ultimately affect the extremities. The prognosis is favorable in the sarcomatosis, the cases yielding readily to arsenic, while in the hemorrhagic variety a few cases only are recorded as cured,⁶ temporary improvement only being the rule. There seems to be no doubt that the prognosis is rendered less favorable in the latter type by the occurrence of hemorrhages.

CONCLUSIONS.

The result of all the foregoing comparisons is that there is no great distinction between the two forms. It rather impresses one that they represent the same process. While some of the cases do not change secondarily, and are, therefore, more amenable to treatment and cure, the majority are subject to secondary changes, rendering the course unfavorable.

DISCUSSION.

DR. W. S. GOTTHEIL, New York—I have had a number of similar but more extensive cases under observation for a long time. The rather careful clinical and microscopic study to which I have subjected them would lead me to conclude that there is not so much difference between them as the elaborate nomenclature of their subvarieties would imply. It is a question whether classification is not rendered more difficult by the multiplication of Latin terms, of which our German colleagues

are so fond. Synthesis rather than analysis is what is now required, lest we lose our way in the terminologic forest. For ordinary purposes I recognize three varieties of sarcoma of the skin. The first is that slightly malignant, superficial growth called sarcoid by Boeck. The second is the localized sarcoma, either primary in the skin or secondary to sarcoma of other organs. The third includes the idiopathic, diffuse sarcomas, pigmented or white. In the present state of our knowledge of the subject I do not believe that variations in color, course, etc., justify us in subdividing maladies which are microscopically almost identical.

DR. M. B. HARTZELL, Philadelphia—I have just one word to say of the character of the so-called sarcoma cutis. Personally I have doubted whether all of these cases have a right to be called sarcoma; if so, then they differ from the surgeons' sarcoma. What the surgeons class as sarcoma is rapidly destructive and rapidly terminates in the death of the patient, but the so-called sarcoma of the skin frequently lasts for years. As has already been said by the previous speaker, the confusion in the use of terms is already great enough without adding new names. We ought to be slow to believe that all of the so-called sarcoma cutis is actually sarcoma. I recall a case that was exhibited at a clinical meeting of the American Dermatological Association as sarcoma in which there was simply extensive slate-colored discoloration of the skin extending to the sclera. We call many of these cases sarcoma because microscopically they look like sarcomatous tissue, but they are probably often something else.

DR. LIEBERTHAL—In reply to Dr. Gottheil I wish to say that in my paper there was neither an attempt made to multiply terms nor to introduce new ones. The long Latin name did not originate with me, but with Kaposi, and has since been accepted by the dermatologic world. Therefore, I have no apology to offer for repeating it before a body of dermatologists most of whom have a national as well as an international reputation and are familiar with it and its interpretation. As long as there is no better name suggested and accepted we do well to let the old one stand in order to avoid confusion.

Regarding the remark made by Dr. Hartzell, I would refer to the essay mentioned in my paper in which Kaposi defends his standpoint concerning the name applied by him to the first form. I did not attempt to solve the question of the place to be assigned to it in pathology, but only entered into the consideration of the similarities between the two forms.

Clinical Report.

SEVERE BRAIN INJURY WITHOUT FOCAL SYMPTOMS.

WILLIAM A. DAVISON, M.D.
BRIDGEPORT, CAL.

The Injury.—July 8, 1902, at 7 p. m., E. L., male, aged 27, had an iron bolt, with a one-inch square top on its end, driven by direct violence through the vault of the cranium. The bolt cut through his hat and scalp, crushing in at least one square inch of the frontal and nearly as much of the left parietal bones, carrying the fragments deep into the brain substance. A triangular piece of left parietal bone, one inch wide at its base and one and one-half inches long, was broken down and rested on the brain. The front edge of the wound was one and one-half inches in front of the coronal suture, a little to the left of the median line of the frontal bone, extending across the median line probably one-half inch, thence backward across the coronal suture into the left parietal about one inch. It thus made an oblong opening about one and one-half by two inches, with jagged edges.

The brain injury involved the superior portion of the first, second and fourth frontal convolutions, the ascending parietal, the superior parietal and probably the superior sylvian convolutions of the left side, the superior portions of the first frontal on both right and left sides, the superior portion of the ascending, and the anterior portion of the superior parietal lobes of both sides.

Treatment.—The course of the wound was slightly to the left. How deep the bolt penetrated I did not have the necessary curiosity to ascertain, but was satisfied to calculate by the size of the opening that there must be buried in the cerebrum the fragments of a section of bone measuring one and one-half by two inches. The conclusion was verified later. I irrigated and removed all visible bone fragments (save that of the left parietal) and such invisible pieces as were easily detected by gentle application of the probe. On removal of the pieces of bone, brain matter and blood clots came away. The triangular piece of the left parietal was elevated and left *in situ*. The bolt had not remained in the wound.

Receipt of the Injury.—No one witnessed the accident and the patient could not tell how it happened further than that he was leading a saddled horse under a wire clothesline attached at each end to a post—at one end by this iron bolt, which inflicted the blow. The clothesline caught under the pommel of the saddle. The post with the protruding bolt was broken off at the ground and hurled some feet away. The man was thrown to the ground, from which he was seen arising by his wife, who at this juncture happened on the scene. With her assistance he walked fifty feet to his bed.

Symptoms.—Hemorrhage was free but not excessive. There was some shock and for a time semi-consciousness; no loss of

Diagram of injury. The lines marked A—A represent the skull fractures.

any of the senses. There was an indisposition to talk, but at all times he would speak if urged. There was also acute, lancinating pain in the front of the head, scanty secretion of urine and little desire to pass water for a day or two. I could not say there was paralysis, for the fluid being scanty and high-colored, I did not allow him to retain it longer than eight hours without use of catheter. The bowels were constipated, but yielded readily to purgatives. I did not consider the bladder or rectal torpor more than one often finds with active men confined suddenly to bed. There was no motor nor sensory paralysis at any time, in spite of the fact that he lost at least a tablespoonful of brain substance from the motor area. From beginning to recovery the temperature never exceeded 99.6. The pulse varied from 40 to 70 for the first ten days and was very weak. This was combated with 1/50 gr. sulph. strychnia hypodermically.

After about ten days the pulse rallied and gradually resumed its normal force and activity. There was no change in the pulse beyond its slow and weak action. The pupils were not markedly affected at any time, but for a day or two were probably not so sensitive to light as in the normal state.

After-Treatment.—For several days small pieces of bone presented themselves and were removed. Irrigation of hot borated water, borated gauze dressings and sulph. strychnia as indi-

ated constituted treatment; he was kept perfectly quiet and given liquid diet. Eighteen days after the accident the brain was granulating nicely, and there was a very light discharge of a non-purulent nature. At this time I closed one-third of the scalp wound with a deep silk suture. The mental condition was good, and the patient was doing well in every respect, which condition has continued. The surroundings were extremely unfavorable. From the beginning to the eighteenth day there was not a drop of pus and no antiseptic was used save borax. I was ably assisted throughout the case by Dr. J. H. O'Connor.

Why there were no more symptoms is the strange part of the case. Why the man did not die after such an injury is a surprise, and why he had so few symptoms of injury to the brain substance is a greater one.

Later.—At this writing (September 26) he is to all appearances in his normal health, with unimpaired senses and motor power, and intellectually unchanged.

New Appliance.

A NEW INGUINAL BANDAGE.

JAMES CHAMBERS PRYOR, M.D.

PASSED ASSISTANT SURGEON, UNITED STATES NAVY.

WASHINGTON, D. C.

Several years ago the writer commenced using a bandage which he originated—so far as he knows—and which has at times been called the "Pryor bandage."

METHOD OF APPLICATION.

Standing in front of the patient, and holding a strip of two or three inch roller muslin bandage, two and one-half yards long, and the dressing being in place, the bandage is applied as follows:

1. Apply the middle of the strip of bandage to patient's vertebral column at the waist.
2. Carry ends of bandage forward about the waist.
3. Holding the extremities taut, carry one end entirely around the other, making a "round turn" or an "elbow hitch." The result resembles an X with one of its component parts completely wrapped around the other.
4. After twisting it as described, carry the inner extremity inside and the outer extremity outside the thigh and unite the ends with a knot, safety pin or other appliance.
5. The dressing (which lies under the intersection of the arms of the X, if the bandage has been properly applied) may now be fastened to the bandage with safety pins, and the dressing is complete.

ITS USES AND ADVANTAGES.

As the writer has demonstrated the usefulness of this bandage in practice, in the U. S. Naval Hospitals at New York, Mare Island, Cal., Newport, R. I., and on naval vessels to which he has been attached, he feels that the above description may be of value to those who are using surgical dressings. It is not claimed that this bandage can wholly replace the time-honored and effective spica or figure-of-eight, but in many instances it may be substituted with a real gain in efficiency.

In applying fixed dressings it is not so efficient, but even here it may be used with splints. For checking hemorrhage it forms a most excellent method of compression. With a suitable pad it makes an excellent temporary truss, and at this writing it is being used in this manner on two patients on the U. S. Battleship *Massachusetts*.

It may be applied effectively with a smaller expenditure of material than any bandage known to the writer, the ratio being as one tour of a spica is to a complete spica. Therefore, where economy is a consideration it may be used to advantage. The ease with which it may be applied commends the bandage at once. Its application requires a minimum of handling of the patient. It may be applied as quickly as any known bandage. It is lighter and more comfortable than a spica, and it does not become so wet with perspiration as does a spica in hot weather.

For ambulant or convalescent patients this bandage is not so cumbersome and does not restrain their movements; there-

fore, it does not interfere with the performance of any light duty for which the patients are not otherwise incapacitated.

Although its application to the groin is the only one here described, its field of usefulness is by no means restricted to the inguinal region. When the principle has once become fixed in the mind its wide range of application immediately becomes apparent, and it is seen how it may be applied in retaining a dressing on a limb, the trunk, axilla, female perineum or genitalia, etc.

The simplicity of this bandage, the facility and rapidity with which it may be applied, and the small quantity of material required, seem to the writer to make it especially adapted to emergency work or to field and military surgery.

SUMMARY OF THE ADVANTAGES.

To briefly summarize, this bandage is 1, economical; 2, easily and quickly applied and with a minimum of incon-

venience to patients; 3, cooler than a spica and not so cumbersome; 4, applicable to many parts of the body; 5, a substitute for a truss in hernia; 6, an effective compress, and 7, especially adapted to emergency or military surgery.

U. S. S. Bancroft.

Raise the Standard of Fees.—A Western contemporary, the *Alkaloidal Clinic*, advocates a general agreement on the part of physicians to raise their fees in accordance with the enhanced prices of the necessities of life which have obtained of recent years. With some conditions and limitations we heartily vote aye to this resolution. The first condition would be that the fees of the physician are those that should be raised—the physician, we mean, as distinguished from the surgeon and the specialist. The internist, the general or family physicians, constitute the most important but the most neglected class of the profession. We have conspired with the thoughtless and melodrama-loving public to give all the honor and all the profits also to the surgeons and specialists. If the profession is to make any common stand for better wages, it must be for the sake of the general physician. His work is worth just as much as that of the operator, but he does not receive one-tenth, and in many cases, not one-hundredth as much. In the second place the movement to increase the fee should at first chiefly consider the country physician, as distinguished from the city man. Either because the number of cases is greater or other means of livelihood are obtainable the city physician does not suffer from low and uncollectible fees as does his country brother. The newly-aroused professional consciousness must show conscientiousness and the love of justice, or it will not endure.—*Amer. Medicine*.

THE HEALTHFULNESS OF COAL MINING.

A number of statements recently made in regard to the unhealthfulness of the miners' occupation suggest a reference to the authoritative utterances on the subject and to statistics. These do not exactly confirm the statements that have been made, and may be a surprise to some who have not investigated the matter. Naturally one would not expect the business of a coal miner to be an especially healthful one; the darkness in which he labors, the frequently constrained and unnatural posture, the dust, the gases and supposedly imperfect ventilation, the fumes of explosives, the dampness, etc., all readily suggest themselves as probable causes of physical deterioration and mortality. In old times the physical strain caused by climbing almost interminable ladders was also a matter to be considered. These factors leave altogether out of account the accidents to which the miner is exposed. It is not surprising, therefore, to most people that the recent testimony before the coal-strike commission should have been so positive as to unhealthfulness of the miners' life—it falls in naturally with their preconceptions.

When, however, we investigate statistics or consult authorities another aspect of the case is forced on us. Aside from accidents, coal mining is said to be a distinctly healthful occupation by those who have considered the subject. Thus Louis¹ says: "Coming lastly to the subject of the diseases of miners, it may first of all be stated that mining is a distinctly healthy occupation. The mortality of all males in Great Britain during the years 1890-92 was 18.74 per 1,000, out of which 0.87 deaths were due to accidents, leaving 17.87 per 1,000 due to what may be termed natural causes. On the other hand, the mortality among coal miners from all causes for the same period was 12.33, that due to accidents being given as 2.00, making the death rate due to natural causes only 10.35 per 1,000." He gives as reasons for this that there is a sort of natural selection at work, that those who find the work too hard drop out, and while the labor is arduous, it requires only steady, moderate exertion, the hygienic conditions in the (English) mines are generally good, the ventilation fair, the temperature equable, the miner is not exposed to the inclemencies of the weather and the place where he works is usually dry. The English coal miner, if industrious, he says, can always earn a wage ample

enough to keep him in fair comfort and to supply him with all the necessities of life. The inhalation of coal dust is irritating to the lungs to some extent and the constrained position in kirving or cutting under has its disadvantages, but these do not seem, in his opinion, to seriously counterbalance the hygienic advantages that otherwise exist. The English coal miners are far better off as far as health is concerned than the English metal miners as shown by statistics. One important cause of needless lung disease among them, he thinks, is their universal custom of walking home in their damp and dirty pit clothing instead of changing at the mine. Where conveniences for changing and bathing have been provided they have been always rejected.

We have not the corresponding authoritative figures and statements for the American coal miners, but we have the mortality statistics as given in the U. S. Census Reports (Vol. III, part 1, p. 154). Here we find that miners and quarrymen included together had a total mortality in 1900 of 5,895. Taking the four chief fatal disorders or classes of diseases we find the figures distinctly favorable to the miners. Thus they lost by consumption less than one-tenth of their total mortality as against over one-ninth among farmers and agricultural workers and over one-eighth among professional men, merchants, common laborers, and between one-sixth and one-seventh in manufacturing employes. Their proportion of deaths from pneumonia was about the same as that of agriculturalists and common laborers, and rather greater than that among most other classes of workers, while that from heart diseases and disorders of the nervous system was among the lowest in all occupations. Only in accidental deaths does mining industry have a specially bad preëminence, and here it is exceeded by the railway service, the percentages being 34 and 39 respectively of the total mortality. The small mortality from heart disease would not indicate any special prevalence of acute rheumatic affections, at least, during active life.

In Newsholme's "Vital Statistics," a standard British authority (1899), coal miners in Derby and Nottinghamshire stand high in the list as to expectation of life, being only surpassed by farmers, agricultural laborers, teachers, etc., but in Lancashire take a considerably lower place, a little below physicians and tailors and just above law clerks, butchers and printers. This would indicate a considerable difference in the conditions in the two localities, but in neither case is coal mining included among the most unhealthy trades. As regards special disease mortality the coal miners lead in bronchitis, of which, however, the aggregate mortality is small, while their loss from phthisis, the most fatal disease, is comparatively slight. A separate table is given of the ratio of mortality in occupations involving the breathing of dust-laden air, and in this coal mining and corn milling are bracketed together among the healthier occupations. Textile manufacturing, quarrying, iron and steel working are apparently much

1. "Dangerous Trades," recently published, edited by Thomas Oliver, M.D., the most recent standard work on the subject.

more dangerous from this cause, while cutlers and pot-
ters are at the worst end of the list.

The accidents of mining are, of course, a serious risk, but it appears from Louis' showing that they are largely avoidable. This is shown by the much lesser proportion in some countries than in others where the legal and other oversight is less strict and by their greatly lessened frequency with enforcement of precautionary regulations. In Great Britain they are apparently much less frequent than in the United States and are less common than formerly, while they are still rarer in Germany. There will always be, among any large number of working men, some reckless ones, and such can easily run up the accident list unless weeded out by the employers or by the general action of the others or constrained by rigidly enforced regulations.

It would seem probable, the miners' life being a laborious one, that it would cover only a certain number of the years of greatest vigor and that this would affect the statistics of mortality. To some extent this must be admitted, yet we find in the census mortality statistics nearly one-seventh of the deaths of miners are at 65 and over, and more than one-fourth over 55. As the mortality rate is not high, it would appear that while many continue at their occupation after middle life, a large number must go into other trades or retire altogether, like the bookkeepers, drummers, railway employes and clerks, who also show a proportionately small mortality at advanced ages. There are other employments that show a much greater mortality but still have a decidedly larger proportion at advanced ages.

It must be remembered that the mortality statistics of the U. S. Census include miners of all kinds, many of whom are engaged in much more unhealthy work than coal mining. They also include quarrymen, whose work, according to the English figures, is in some respects less healthful than that of the coal miner. It is unfortunate that we have not the data to exactly parallel these figures in this country and Europe, but it is quite possible that the results would not be materially affected. Taking it altogether the facts collected from all available sources seem to indicate, what we have hardly expected, that the occupation of coal mining is not either relatively or absolutely unhealthful as compared with the majority of other means of gaining a livelihood. It has its inconveniences and hardships and is exposed to special dangers from accidents, but these can be minimized by proper care, appliances and legal regulations. In Great Britain the mortality from coal mining from this cause is given by Newsholme as less than twice that in the general population. The special diseases to which miners are liable seem also to be largely preventable, thus greater care in changing the equable atmosphere of the mine to the extremes of heat and cold outside would probably reduce the proportion of respiratory affections, such as asthma, etc., that are now claimed to be incident to the occupation. These are the natural deductions from the data furnished by the authorities above quoted and which can not well be discredited.

AS TO ALCOHOL.

There are few problems of greater importance than the place that should be accorded alcohol as a beverage, a food and a therapeutic agent respectively. At the outset the question arises: Is the use of alcohol for any or all of these purposes on the one hand desirable, useful and free from danger, or, on the other hand, undesirable or unnecessary or even injurious; and the answer must be shaped from a knowledge of the physiologic actions of the substance in question. Now, so far as is known, alcohol belongs in the group of physiologic agents known as sedatives or narcotics, such apparent stimulation as it gives rise to being due rather to paralysis of inhibition. Alcohol is an irritant of tissue and, in sufficient amount and concentration, a protoplasmic poison.

As a beverage alcohol is unnecessary, as this purpose can be at least as well fulfilled by a number of other substances quite devoid of danger. The sense of well-being to which alcohol gives rise is due in part to loss of the sense of responsibility, and is therefore not to be lightly invited. Such value as a food or as a producer of energy or of heat as alcohol has is possessed by a large number of other substances incapable of harm, while the rapidity with which alcohol, when taken in moderate amounts, is consumed in the body is offset by the attendant interference with metabolism. As a therapeutic agent alcohol will find its indications when its physiologic effects are desired, and these can not be better induced, or with less danger, by any other means.

This entire subject has received generous and frequent discussion in recent years, and it would appear from the published communications bearing thereon that the view as to the inutility of alcohol for many of the objects for which it has long been employed is gaining increased acceptance. The November number of *The Practitioner* contains a symposium by distinguished English authorities on various aspects of the use of alcohol. The editor's own attitude appears to be one of tolerance or neutrality. In the opinion of Sir Samuel Wilks, who has himself used wine moderately as a beverage, alcohol is a good medicine and an important article of diet, but he holds that the circumstances and the limitations of its employment should be determined by the medical man. Sir Henry Thompson relates that early in life he personally secured relief from hemicrania and rheumatism by abstinence from alcohol. On attempting, at the age of 75, to resume the use of wine he found the effect to be unquestionably injurious. Sir Wm. Broadbent insists that alcoholics should be regarded as medicines and prescribed with the same care and in the same definite way as the most powerful remedies.

In discussing the pathology of alcoholism Dr. G. Sims Woodhead points out not only that the excessive use of alcohol induces cirrhotic changes in kidney and liver, but also that pneumonia, for instance, in alcoholic patients assumes a most virulent form and often ter-

minates fatally, marked fatty degeneration being found in various organs, and that a history of alcoholic indulgence is often an antecedent factor in the etiology of a number of diseases of the nervous system. The deleterious effects of alcohol are due to interference with nutrition and to gross degeneration of cytoplasm. These are most marked perhaps in the fibers of the heart muscle, but in advanced cases they appear also in the muscular coat of the blood vessels, in the liver cells and sometimes in the excretory cells of other organs. Fibrosis and calcification may result as secondary changes. Furthermore, it has been demonstrated that indulgence in alcohol predisposes to infection and that alcoholics attacked thereby resist its ravages less well than do abstainers. Dr. Woodhead always has been an abstainer, and he has found that as an athlete, as a student and as a worker he has been able to accomplish the tasks that have fallen to him with as little effort as his fellows, if not with less effort.

After pointing out the truly enormous annual expenditure for alcoholic beverages in the United Kingdom, together with the resulting pauperism, crime, destitution and disease and the losses in labor and due to accident, etc., Dr. Jas. Edmunds cites the experience of the United Kingdom Temperance and General Provident Institution, which for more than fifty years has insured abstainers and non-abstainers in separate departments. It has been found that the number of deaths expected, the number that actually occurred and the policy claims paid were all more than 25 per cent. greater in the case of non-abstainers than in that of abstainers. Furthermore, the statistics of the registrar-general for England and Wales show a much higher mortality among persons engaged in occupations that favor indulgence in alcohol. Testimony of an allied character is presented by Dr. J. J. Ridge and Mr. Francis Vacher. As to the part that alcohol plays in surgery Mr. Pearce Gould holds that it is altogether an injurious one. Mr. J. Milne Bramwell cites the results obtained in the treatment of 76 cases of dipsomania and chronic alcoholism by means of hypnotic suggestion. Recovery ensued in 28 cases, improvement in 36 and failure in 12.

As will be seen, the symposium in *The Practitioner* constitutes a strong document in favor of temperance, if not abstinence, with respect to the use of alcohol. Whatever the measure of doubt or uncertainty in which the question is involved that attitude would appear to be at least a safe one. It will not be contended that alcohol is necessary as a beverage or as a food, and it can therefore be dispensed with for such purposes. As to its therapeutic employment, there may be reasonable difference of opinion, and we may wait for further evidence, but at this point before reaching a final conclusion.

he works is **TUBERCULOUS CERVICAL ADENITIS.**

industrious, by Dr. Freeman in the present number of

1. "Dangerous" AL appears especially timely, since various

writers have recently advocated earlier and more radical operative measures in the treatment of tuberculosis of lymph glands. Tuberculous cervical adenitis is a disease which comes under the physician's care with relative frequency, being especially prevalent among city children with unhygienic surroundings. Swelling of the cervical lymph glands is common in children as a sequel to various inflammatory processes in the nose, pharynx, mouth, tonsils, ears and scalp. The swelling may immediately follow a single acute disorder, but it is frequently due to repeated slight inflammations and chronic catarrhs of the nasopharyngeal mucous membranes. Such enlarged glands tend to disappear, as the child becomes older. If tubercle bacilli gain entrance to these enlarged glands, they find favorable conditions for multiplication, and tuberculous adenitis is often implanted on a previous benign swelling. It is most likely that the tubercle bacilli usually enter the glands through the lymphatics which pass from the inflamed mucous membranes above mentioned, and since typical tuberculous ulcerations are rarely found at these points it has been assumed that the bacilli pass through the mucous membrane or through trivial wounds without causing any tuberculosis at the place of entrance. The disease usually progresses so slowly and terminates in spontaneous recovery in so many cases that it is often difficult to know what is best to be done in regard to treatment. In every case the patient should be given the advantage of the best hygienic surroundings. Tonics, cod liver oil, creosote, etc., should be administered for their general effects. Any local disease in the nose, throat, etc., should receive appropriate treatment. The application of iodine and other irritants to the skin overlying the glands is to be condemned; no good results follow such measures and they seem to do harm by encouraging inflammations about the glands. Injections of various antiseptic substances have also been found to exert no favorable influence, and they sometimes appear to render subsequent removal more difficult. If the glandular changes are limited, the enlargement being comparatively moderate and showing no tendency to break down, the general advice is to watch the progress of the disease in the glands, and to make every effort to improve the general condition of the patient. If the disease shows a tendency to progress, especially if the enlargement has attained considerable size and persisted for some time, operative measures must be instituted.

The surgical treatment of tuberculous cervical adenitis has been gradually elaborated during the past twenty years. In 1893 the subject was discussed at the meeting of the British Medical Association, and Allbutt, Teale and others urged more general operative treatment in this class of cases. Teale declared "the ugly scars and unseemly depressions, once so familiar in scrofulous necks, should be deemed an opprobrium of surgery; whilst to delay operation until the skin is

thin, red and ready to break down, or has already given way, should be looked on as mischievous trifling." The operative treatment advocated at that time consisted largely in incising and scraping caseating glands, and many were inclined to adhere to conservative measures as long as possible, leaving surgical interference as a last resort. In 1899 W. Watson Cheyne,¹ in the Harveian Lectures, strongly advocated complete removal, not only of the very large and caseating glands, but also of all adjacent glands which are not perceptibly enlarged, together with the surrounding fat, and all tissue involved by extension. Whenever the tuberculous mass could not be satisfactorily separated from the internal jugular vein, he advised the removal of a portion of the vein between two ligatures. This latter procedure he found necessary in all cases in which there were sinuses, and practically all cases in which suppuration was present. The highly satisfactory results of such radical operative treatment of tuberculous adenitis in the hands of the leading surgeons have led to a more general adoption of similar measures. The recent publications by Parker² and Mitchell³ indicate that experience with extensive material impresses the observer with the value of thorough operative removal of all infected tissues in these cases. Parker urges more frequent and thorough operation in the milder cases, thus reducing the number of advanced and extensive cases calling for treatment.

While tuberculous cervical adenitis is primarily a local disease, and not extremely serious nor rarely proving fatal in itself, it bears a certain definite relation to pulmonary tuberculosis, and tuberculous glands are a constant danger, being a source from which tuberculosis may spread. Permanent recovery follows proper removal in over 70 per cent. of cases, and tuberculosis of the lungs, after complete removal of the glands, is comparatively rare. There is no doubt that operative treatment in these cases should be instituted early, at a time when removal can be effected with comparative ease, and that the excision should be radical in all cases.

THE STUDY OF PALSIES.

A review of the large and increasing statistics of infantile palsies applying for treatment in the metropolitan clinics of children's and nervous diseases shows plainly that the cause and prophylaxis of these disorders are in need of more minute study. The morbid anatomy and the manner of production of the spinal type is fortunately well known from the more recent work of Semering, Goldscheider, Medin, Strümpel and Zuppper, but its minute pathology and pathogenesis are still in doubt.

A question still under discussion is, are they primarily parenchymatous or vascular in their inception? The general trend of modern research is in favor of the latter theory, while the secondary changes are consid-

ered to be interstitial and parenchymatous. Opinions appear about equally divided between the theories of the autotoxic and organismal cause of the primary lesion, but the force of its epidemic occurrence is in favor of the latter.

While preventive medicine seems on the eve of triumph in the spinal type of palsy, it is far distant in the cerebral form. Here the problem is a disheartening one. Spinal architecture and function is now well known, but that of the brain is in its infancy. The nature of the earliest changes in cerebral palsy is especially obscure, notwithstanding its terminal pathology is quite clear. The thrombophlebitic, interstitial and hemorrhagic changes are all secondary to an infectious element. Muratow,¹ in his recent work, strongly contends for the non-suppurative parenchymatous character of the lesion. The author particularly insists on the para-infectious nature of the disease process. From clinico-pathologic data he believes it is shown to be due to a toxin, not to an infectious organism itself. Coincident to this work we find the encephalopathy type of lesion is still urged by Strümpel, and that this belief is current in German medicine, and furthermore. Strümpel's assistants have but recently found new facts to substantiate the original contentions of their chief.

Detail studies in the cerebral palsies, especially on athetosis and allied disorders of motility which follow in the wake of the original lesion, appear from time to time and are of considerable interest. For a number of years it has been known that rare cases of paradoxical pseudo-hypertrophy may occur in cerebral palsy, but this has rested on the rather slender argument that the choreic paresis present causes the hypertrophy by agitation of the partly paralyzed parts. The recent review of the matter with report of five new cases made by Clark² has also shown that epilepsy may accompany or replace athetosis, but this hardly explains the hypertrophic state of soft and bony parts of the trunk, not in agitation either in athetosis or epilepsy, as recorded by the older French writers.

It has been conclusively proven by Batten that the muscle spindle has no other than sensory functions, and that it suffers no material alteration in brain or spinal palsies in children. We must, therefore, look to the nature of the cerebral lesions for an explanation of all the phenomena attending these paralytic disorders. The importance of being able to diagnose the seat, nature and degree of brain damage is rightly emphasized by Clark. But before we shall be able to do this to any degree of satisfaction a more exact anatomy and physiology of the brain, and especially of the cerebral cortex, must point the way.

CALIFORNIA STATE JOURNAL OF MEDICINE.

Volume I, No. 1, of the *California State Journal of Medicine* is just received. It is the journal of the Medical Society of California, and will be issued monthly in

1. Brit. Med. Jour., Dec. 16, 1899, 1659.

2. Brit. Med. Jour., Oct. 25, 1902, 1312.

3. Johns Hopkins Hospital Bulletin, July, 1902, 161.

1. Monatschrift für Psychiatrie und Neurologie, May, 1902.
2. Journal of Nervous and Mental Diseases, November, 1902.

place of the annual transactions. In the editorial announcement we read:

"The Journal will be the partisan of no one and nothing, save only and always an energetic partisan for honest, legitimate, ethical practice of the regular profession, for truth and right, and, first, last and all the time, for organization, and again organization, of the regular profession of California into a united body—the State Society."

The first number is a credit both to the editorial committee and to the Medical Society of the State of California.

RECOMMENDATIONS FOR THE NAVY.

The report of the Surgeon General of the Navy contains, besides the usual matter, one or two propositions worthy of special note. One is the recommendation of the provision for a corps of female nurses to act in the large naval hospitals. Army experience has shown the advantages of such a corps, and there ought also be occasion for their services on hospital ships. It would also relieve the hospital apprentices now employed, for sea service, as the Surgeon General suggests. The military female nurse appears to be a permanent institution in the Army, and there is no good reason why her services should not be secured to the naval branch of the service. Another suggestion, though without formal plans, recommended is that of a naval tuberculosis sanitarium, thus also profiting from the Army experience. The bureau has the subject under consideration and hopes to be able to offer definite plans in the near future. The need of increase of the medical corps of the Navy is emphasized, as the work has increased and the present law does not provide for a sufficient number of medical officers. There are no vacancies and the corps is undermanned and overworked. It is a proper subject for the consideration of Congress, as with our naval increase there should also be a corresponding increase of the medical corps or the whole body will suffer. Naval line officers do not always appreciate their own needs in this respect, but it is to be hoped that their influence will also be exerted for the Surgeon General's recommendations. Our new Navy should be a model one in its medical as well as in all other departments.

THE MECCA PILGRIMAGE.

It is an evidence of the advance of modern medicine and the benefits that it has conferred on mankind that the epidemics that were so fatal even a few decades since are now little to be feared by civilized communities. Thus cholera, which raged in the United States and Europe even later than the middle of the nineteenth century and only eleven years ago in the city of Hamburg, now gives little concern to sanitarians, as we know how to avoid it, even in the centers of its prevalence. There are good reasons, nevertheless, why we should not neglect precautions; there are many, even in the most highly civilized communities, who from their habits and prejudices can furnish food for epidemics of even the most preventable diseases. It is therefore not a matter of indifference to us, aside from all general humanitarian considerations, that cholera rages in Egypt or

Eastern Asia, and anything that can be done to prevent its continuance should not be neglected. It is to be presumed that in the Philippines, India, China and Japan all that can be done with the material of their populations is being done, but in the nearer East the case may be different. The Mecca pilgrimage has always been the disease breeder and disseminator *par excellence*, but fear of stirring up religious fanaticisms has heretofore kept Europeans from interfering with it except in a very partial and inefficient way. Now that we know better how to control the disorders that have heretofore been formidable as epidemics, the question arises whether it is not an urgent duty of the powers that have most to do with this, as rulers of adjacent territories or of those that furnish the pilgrims, to take up the matter and either enforce needed sanitation or, if necessary, even stop the pilgrimage. The latter step would, of course, be only one of last resort, but its possibility should be considered. It is useless to expect any Moslem powers to take the matter up, and their promises are worth nothing. In the meantime cholera is devastating Egypt and other Mohammedan countries and the dangers of its extension are always present. Though most civilized countries will escape, the present state of affairs is the cause of hundreds of thousands of needless deaths and an interference with commerce and the world's progress. The Mecca pilgrimage, as conducted, is an ever-present annual peril to the welfare of the world.

THE FOOTBALL MORTALITY.

The football season is now over and leaves behind it a very respectable record of casualties, enough to supply a respectable Spanish-American war, and only second to the Fourth of July mortality. Thus far the returns give 12 deaths, several fatally injured and over eighty seriously injured, smaller items, such as sprains, bruises, torn ears, loss of teeth, etc., not enumerated. The query whether the game is worth all this naturally suggests itself. There is something in most of us that makes danger a sort of relish to our pastimes, and it is perhaps to this barbaric element in our natures that some of the world's progress is due. Professionally, however, we can not approve of anything so unsanitary even in a purely traumatic way, and it would seem that something might be done by those in charge of college athletics at least, to modify the roughness of the game and somewhat reduce its risks. Among the serious casualties of the game this year we have fractured skulls, injured spines, brain injuries resulting in insanity, as well as broken legs, ribs, collar-bones, etc. To be a cripple or lunatic for life is paying high for athletic emulation. Besides this, there is another side of the question, a moral one that deserves consideration. There is what one may call "dirty football." We hear of slugging players, of those that directly aim to injure players or aggravate existing injuries so as to disable them, and the umpires do not seem to consider this a sufficiently serious matter. The reports of casualties give plenty of evidence of this; we have the records, "kicked in the head," "stabbed in the back," among the other injuries reported, showing that the game is made absolutely murderous at times. It is hard to speak mildly of such outrages, but if the rules were made and en-

forced that any "dirty work" lost the game to the side indulging in it or even severely penalized it, much good would be done. At present it almost appears that football authorities condone this sort of thing, and certainly they do little to show that they are not willing to profit by it. There is little difference in this from criminal manslaughter or murder if death should result, and all who do not actively discourage it are more or less responsible. It may be that we must have more or less unavoidable risk in football, for it is a rough game, but brutality is utterly needless and deserves the severest condemnation and condign punishment. There is no use of making a rough game a murderous one.

Medical News.

CONNECTICUT.

Personal.—Dr. Walter L. Lay, Norwich, will practice in Middletown; his successor at the Backus Hospital as senior house physician is Dr. F. A. Emmett, and the vacancy caused by the latter's promotion has been filled by Dr. David Getchell, Oldtown, Me.

Physician Fined and Appeals.—Dr. Anthony J. Hill, Torrington, charged with having practiced medicine without registering or taking the examinations requested by the state law of 1897, was found guilty, November 19, and fined \$100 and costs. He took an appeal to the Superior Court. Dr. Hill has long been a resident of Torrington, but some time ago gave up his practice to a considerable extent. About a year ago he commenced active work again.

Smallpox.—From the report of the Connecticut State Board of Health, we quote the following:

One of the most notable facts relating to the health of the state during the past year, was the widespread prevalence of smallpox. Cases were reported from 34 different towns, including every county in the state.

In only a few places did it assume the character of an epidemic, although regarded as the most contagious of all diseases.

In two ways these outbreaks gave testimony to the protective power of vaccination: 1. Connecticut, one of the most densely populated states and in intimate relation with the rest of the country, was slow to entertain any cases of the disease. This exemption can be explained only because so large a proportion of the inhabitants have been rendered immune by vaccination.

2. The spread of the disease has been almost wholly among those who were never vaccinated, or who were vaccinated so long ago, that its protective power had been impaired by time. In still another way its value has been verified, by the prompt arrest of the spread of the disease wherever a general vaccination has been practiced.

There were 323 cases reported during the year ended October 1, of which only 22 were fatal, giving the surprisingly low death-rate of 6.8 per cent. In all the literature there is no record of an epidemic of so mild a type.

In the three largest cities in the state, where general vaccination is observed, there were only 16 cases.

ILLINOIS.

Jo Daviess County Loses Suit.—In the case of Dr. George A. Staples et al. vs. the County of Jo Daviess, for services rendered a poor patient of East Dubuque, the jury found for the plaintiffs and awarded \$500 for services rendered. The original bill was for \$300 but this the county board of supervisors refused to pay, and offered to settle for \$150.

Suicides.—Native Illinoisians do not often commit suicide. Out of 35 who killed themselves in Chicago, 19 were foreigners and 12 were natives of other states. Cook County has the greatest number; St. Clair County, which has a certain proportion of the St. Louis suicides, ranks second; Sangamon County, third; Peoria County, fourth, and Vermilion County, fifth.

Chicago.

Funds for Hospitals.—The will of the late Mathews Gottfried bequeaths \$2000 to the Christian Brothers' Hospital; \$3500 to Mercy Hospital, and \$2000 to the German Hospital.

Need of Children's Hospital for Contagious Diseases.—In its latest bulletin the department of health calls attention to the need of a hospital for children ill with contagious diseases, and cites a distressing case in confirmation.

X-Ray Suit.—Suit has been begun by John Bortoli against Northwestern University and Lakeside Hospital for injuries alleged to have been received during the course of treatment

at these institutions with the x-ray; \$12,000 damages is claimed.

Convalescent Home Opened.—A home for convalescent women was opened at 521 West Adams Street, November 22. It will accommodate thirty, and is designed to provide a home for women discharged from hospitals before they are fit to take up their work again.

Suit for Consumption Treatment.—A suit has been entered in the Circuit Court by Frank B. Pease, executor of the estate of the late August Dahlin, against Drs. John B. Murphy and August F. Lemke, for \$25,000 damages. The main allegation of the plaintiff is that a treatment described as the nitrogen monoxid gas method, which it is claimed was invented by Dr. Murphy and applied to Dahlin by Dr. Lemke, materially shortened the life of Dahlin.

Deaths of the Week.—During the week ended November 29, 448 deaths were reported, corresponding to an annual death rate of 12.83. There were 12 fewer deaths from all causes reported during the week than during the week before, and 25 fewer than in the corresponding week of 1901. The significance of this decrease is in the number of deaths (ten) under 1 year of age, and in that (fourteen) under 5 years of age. It is an axiom among sanitary authorities that the death rate under 5 is the best test of the sanitary condition or of the sanitary administration of a locality. Only the increased number of deaths from violence, including suicide, prevents the death rate of this month from being the lowest November mortality rate on record. There were 37 violent deaths reported during the week, as against 25 during the corresponding week of last year. Pneumonia caused 50 deaths; consumption, 40; cancer, 27; diphtheria, 21, and typhoid fever, 19.

False Death Certificates Spread Contagion.—The Department of Health comments as follows on a practice which is alleged to be growing, of the issuance by certain physicians of false death certificates in case of death from contagious diseases:

Another and more culpable, even criminal, cause of the spread of contagion is being investigated by the health department, with a view of presenting the evidence to the medical organizations of the city and to the State Board of Health, which latter body is charged with the enforcement of the medical practice act. This cause is the growing practice among certain physicians of the baser sort of giving certificates of death from contagious disease, in which certificates some non-contagious disease is falsely assigned as the cause. This is done usually at the request of the family, who wish to evade the restrictions of the health department in contagious disease funerals.

The Registrar of Vital Statistics reports to the commissioner that "We have had numerous complaints from undertakers that certain physicians were practicing this deception to a considerable extent, but up to date we have been able to verify only these two cases. We have pressed our preventive work so far as we can with undertakers without having the co-operation of the attending physician. We can control an undertaker, but not a physician. The situation is particularly grave at this time, inasmuch as diphtheria is endemic in this locality—the district south of the C. B. & Q. R. tracks and west of Center avenue to California avenue. The cases of diphtheria reported from this immediate neighborhood began in June with 1; then no other case until August, when there was 1 more; in September 3, in October 15 and in November 22, making a total of 42 cases—over half the total number occurring within the last month. There is no telling how many cases have been concealed, nor how many funerals of contagious disease deaths have been conducted without the supervision of the department for the enforcement of preventive measures against the spread of contagion; but it is evident from this rapid increase of diphtheria—out of all proportion to the increase in other portions of the city—that there is need of greater authority over a certain class of certifying physicians than the department now possesses."

INDIANA.

To Add to College.—The Medical College of Indiana, Indianapolis, has purchased 50 feet of additional frontage on which it will erect an addition to the present college building.

Hammond Board of Health Organized.—The Hammond Board of Health has been organized with Dr. Preston G. Ihach, president; Dr. Cyrus W. Campbell, secretary, and Dr. Thomas W. Kohr, inspector.

Physicians in Indiana.—According to the annual report just published by the State Board of Medical Examination and Registration, there are 5880 physicians in Indiana, of whom 685 are in Marion County.

Indictments for Body Snatching.—The grand jury for the July term of the Marion County Criminal Court has returned indictments against six of those alleged to have been concerned in removing corpses unlawfully, selling them to various medical colleges, and aiding and abetting in the concealment of the corpses.

Charges Against Physicians.—Charles Soultz has entered suit against Dr. Aldine J. Dooley, Marion, for \$5000, alleging

that by the defendant's negligence and lack of skill, the plaintiff received permanent injury to his sight.—Dr. Donald M. Kelley, Brookston, has been sued for \$10,000 damages by Bertha Garrett, who alleges that the defendant attended her for dislocation of the shoulder, and that by his unskilful treatment she was rendered a cripple.

KANSAS.

Personal.—Dr. John D. Freeman has returned to Topeka after six months of study in Europe.

Patient Wins Damage Suit.—In the suit brought by Mrs. Mary Collins for \$3000 damages for alleged malpractice in the setting of a broken arm and shoulder, against Dr. W. H. Mauser, Burden, the jury found for the plaintiff and assessed the damages at \$650.

KENTUCKY.

Louisville.

Health Commissioner's Annual Report.—In his annual report Dr. Maverell K. Allen calls attention to the low death rate of 16.32 per 1000. Among the reforms suggested are additional public bath houses, more sewers, another garbage crematory, and the free distribution of antitoxin. Great stress is laid on the necessity for regular medical inspection of the public schools where the conditions are favorable to the spread of contagious diseases.

St. Joseph's Infirmary.—The golden jubilee of this institution was celebrated November 29. This institution grew out of the old orphans' asylum, established in 1837, on Jefferson Street, and moved to its present location in 1852. Some of the sisters on duty have been at the infirmary for twenty years. The first patient was received Dec. 2, 1852. Among those who have attended patients at the institution have been Drs. Samuel Gross, Erasmus Force, Henry Miller, Austin Flint, Lewis Rogers, T. S. Bull, and David W. Yandell.

War on Milk from Distillery Fed Cows.—The health officer has begun war on the dairymen who feed distillery slop in violation of the city ordinance prohibiting its use. Three dairymen have been indicted in the city court and the Dairy-men's Protective Association has issued a card claiming that "milk yielded by cows fed on distillery slop is of healthful quality, rich in butter fats; in fact, as good or better milk than is produced by cows fed exclusively on dry feed." They claim that the tests of the health department prove this fact, that they feed slop with other feed and submit it to a heat of 160 degrees before it is fed, and that there is no alcohol in the material. The health department is seriously considering the advisability of publishing the names of the dairymen licensed to vend milk in the city and what material is used by them for feed.

MARYLAND.

New Hospital at Cambridge.—Plans for the United Charities Hospital at Cambridge provide for a building with 40 rooms, at an expense not over \$30,000. It is proposed to build on the East Cambridge site.

Approve State Care of Indigent Insane.—At the semi-annual meeting of the Medical and Chirurgical Faculty of Maryland, held at Laurel, November 18, the faculty gave its approval to the state care of the indigent insane, and a motion was adopted that a committee be appointed to take the matter under consideration, and report a plan at the annual meeting for approval and submission to the legislature.

Personal.—Dr. John Ridout has been elected physician to the Charities Association of Annapolis.—Dr. James H. Jarrett celebrated his golden wedding at Towson, November 16.—Dr. Samuel Chase DeKrafft, major and surgeon, U. S. V., who has been serving with the Army in the Philippines for several years past, has been honorably discharged from the service and will return to his former home in Cambridge, Dorchester County.

Baltimore.

Will Entertain Lorenz.—Dr. Adolf Lorenz is expected here this week, and arrangements are being made to give him a warm reception. He will be the guest of the Johns Hopkins Hospital.

Accident to Professor Abel.—Dr. John J. Abel met with an accident at the physiologic laboratory of the Johns Hopkins Medical School, November 21. A bottle of amyl-nitrite exploded, cutting one of the tendons of his right hand and making him very ill from the fumes.

Prospects of the University.—Dr. Eugene F. Cordell addressed the senior class of the University of Maryland, Novem-

ber 22, on the "Past History, Present Needs and Future Prospects of the University." A strong movement is being made by the alumni and friends of the university to reorganize it on a better basis, and to push forward the endowment scheme. Extraordinary efforts will be inaugurated in the near future to raise a large endowment for the centennial which will occur in 1907.

Personal.—Surgeon H. R. Carter, U. S. P. H. and M.-H. Service, Baltimore, has been detailed as representative to the sanitary conference at Cairo, Egypt.—Dr. Ira Remsen of Johns Hopkins University was elected president of the Association of Colleges and Preparatory Schools of the Middle States and Maryland, which met in Baltimore November 16.—Dr. Jennie N. Browne has been appointed assistant medical agent for the South Baltimore District for the treatment of women and children.

Alleged Wrongful Registration.—On complaint of Dr. Eugene McE. Van Ness orders were signed, November 21, requiring Drs. Herbert Richardson, J. Thomas Nelson, William Caspari, Jr., Arthur W. Smith and John Thomas Avery to show cause by December 6 why their names should not be stricken from the register of physicians and surgeons duly qualified to practice medicine in Maryland, kept in the office of the clerk of the Superior Court. It is alleged that the physicians named were wrongfully registered without first having obtained a license from one of the boards of state medical examiners.

Institution for Feeble-Minded.—Plans have been completed for the administration building of the Maryland Asylum and Training School for the Feeble-Minded near Owings' Mills, Baltimore County, and construction has already begun. It is to be the central figure of a group of which two, a cottage accommodating 75 children, and a school building, have already been built, and will have a frontage of 100 feet with wing extensions from each end to the rear, 63 feet deep. It will have accommodations for the superintendent and his family, executive offices and sleeping rooms for teachers and assistants. At the rear, and connected with the various buildings, with inclosed corridors, will be a kitchen and refectory building. The buildings are being constructed of white limestone, and will cost \$50,000.

MICHIGAN.

Typhoid at Prison.—There is said to be an epidemic of typhoid fever at the state prison in Jackson, where 22 cases have occurred.

Tried for Sending Obscene Letters.—"Dr." J. R. Krauth, Cadillac, plead guilty to the charge of sending obscene letters through the United States mail and was sentenced to pay a fine of \$200, or in default to go to jail for 90 days. He paid the fine.

Personal.—Dr. George R. Pray, Ann Arbor, has been appointed physician to the state prison at Jackson, vice Dr. William A. Gibson, resigned.—Dr. G. Parker Dillon, formerly of Grand Rapids, acting assistant surgeon, U. S. Army, has been seriously ill with Malta fever, and has returned to the United States.

Michigan Mortality.—There were 2360 deaths reported during October, a decrease of 188 deaths from the preceding month. The death rate was 11.4 per 1000 population per annum, as compared with 12.6 for September. There were 470 deaths of infants under 1 year; 181 deaths of children aged 1 to 4, and 607 deaths of individuals more than 65. Important causes of death were as follows: Tuberculosis, 162; typhoid fever, 84; diphtheria, 73; scarlet fever, 19; whooping cough, 13; pneumonia, 149; diarrhea and enteritis, under two years, 130; cancer, 104; accidents and violence, 188. A decrease was shown in the mortality from tuberculosis, whooping cough and diarrheal diseases from the preceding month, and an increase in the deaths from diphtheria and pneumonia. Two deaths from smallpox were reported.

MISSOURI.

State Tuberculosis Sanatorium.—The St. Joseph Medical Society, at its meeting, November 12, unanimously adopted resolutions favoring the establishment of a state tuberculosis sanatorium.

Personal.—Dr. Joseph F. Robinson, Nevada, has been elected non-resident lecturer in the medical department of the State University.—Dr. Louis C. Fuller, Kansas City, is seriously ill as the result of a cerebral hemorrhage.—Dr. Edward B. Clements, Macon, has been elected to the state legislature.

Condemn Congulant Clarifiants.—The committee of the St. Louis Medical Society appointed to investigate the water problem of St. Louis, in its report unhesitatingly condemns the use of alum or any other coagulant to clarify the city's water supply. Resolutions were adopted which condemned any attempt to purify the water supply by chemical means, and urged that the water be procured from sources that are naturally pure.

NEW JERSEY.

Personal.—Dr. Frank C. Katherman, Atlantic City, has been appointed surgeon for the Pennsylvania system at Altoona, Pa.—Dr. Frank Devlin, Newark, has been appointed visiting surgeon to St. James' Hospital.

Typhoid in Trenton.—An epidemic of typhoid fever in Trenton is feared. The health officials are said thus far to have found no specific source of infection. Many cases are in hospital and many more suspected individuals are under observation.

Osteopath Fined.—E. M. Herring, Asbury Park, an osteopath, has been fined by Judge Heisley of the Monmouth County Court \$100 and costs, for unlawful practice of medicine. The judge held that the application of hands in the treatment of a disease was a remedy in the same schase as the application of drugs. This is the first case of the kind in the state. The medical law has been sustained by the Court of Errors and Appeals in all cases heretofore tried for unlawful practice.

William Pierson Memorial Banquet.—The William Pierson Medical Library Association at Orange celebrated by a banquet, November 12, the conclusion of its highly successful first year. Profs. A. Jacobi, M. Allen Starr and Dr. J. H. Huddleston were present and delivered addresses. The Hon. Frederick Adams delivered a eulogy on Dr. Pierson. The association now has about 80 members, has a library of 1500 volumes, and a fund of more than \$5000 donated by Dr. Pierson's widow, the income from which will be devoted to keeping up the supply of books for the library. Steps have been taken to increase this fund and also to establish a fund from which the expenses of medical lectures to be given by the best medical and scientific men before the association shall be met.

NEW YORK.

Opposition to Coroners.—The movement against the medical office of coroner has received a new impulse by the appointment of a committee from the New York County Medical Society to investigate and report on the advisability of reorganizing or abolishing the coroner's office. This committee consists of Drs. William M. Polk, J. Winters Brannan and Frank Van Fleet.

Increased Appropriation for Insane.—It is expected that the State Commission in Lunacy will request the next legislature to increase its appropriation for next year by at least \$500,000. The total appropriation for the care of the insane in 1902 was \$4,165,886.66, which was \$340,000 less than the appropriation for 1901. The commission, however, had on hand a large balance and this was utilized last year. This year there is no balance, so an increased appropriation is necessary.

Negroes and Cocain.—William H. Johnson of the Bureau of Labor and Charities has called on the citizens of Syracuse to alleviate the condition of a large percentage of Syracuse negroes. He states that every crime committed in that city in the past two years has been committed by a cocain fiend. He charges this increase to the looseness of druggists who sell the drug openly. Many normal school graduates among the negroes have become addicted to the drug, and there are many who have had to leave school.

Defense of the Accused Eddyites.—In the recent argument on the demurrer to the indictments at White Plains, so many new and interesting legal points were raised by the Eddyites that Judge Platt requested the lawyers to submit briefs. The chief contentions of the defense are: That under the constitution the members of the Eddyite Church have a right to liberty of thought and the use of their faculties; that there is no law which compels medical attendance, and that there is no law compelling a parent to give his or her child drugs.

New York City.

Thousands Offered for Hospital.—Four persons have each promised to the New York Post-Graduate Hospital \$25,000 if the hospital association of the institution shall succeed in raising \$100,000.

Regarding the Late Dr. A. M. Phelps.—At a meeting of a committee of the City Hospital Medical Board, November 22, resolutions were passed expressing regret at the untimely death

of the late Dr. A. M. Phelps, who was for more than thirteen years visiting surgeon to the institution.

Personal.—Dr. Ogden C. Ludlow has been appointed visiting physician to St. Joseph's Hospital.—Dr. Gertrude N. Light has been appointed a sanitary inspector.—Dr. Clinton H. Catherwood, who has been absent in the West for some time because of ill-health, has resumed practice.

Home for Nurses.—As a result of plans prepared by friends of the New York Hospital, the graduate nurses of this institution are to have a clubhouse and home. The building, including the purchase of a tract of land centrally situated, will cost \$300,000. The building will accommodate 130 nurses.

New Hospitals Opened.—St. Bartholomew's Clinic, under the charge of Dr. Sinclair Tousey, has moved into its new building erected by the munificence of Mrs. Joseph C. Hoagland of Brooklyn, who not only bought the site and erected the building at a cost of \$300,000, but also agrees to assume the expenses of its maintenance.—The new Bradford Street Reception Hospital, where all East New York emergency cases will be treated, was opened November 24.

Fined for Infractions of Law.—Dr. Agnes Karlstoe was convicted, November 26, of practicing medicine without a license, and fined \$150. She paid the fine and promised to leave the country. On the same day Dr. Luigi de Ambrosio was convicted of the same offense and fined \$250. Dr. John Lo Pinto was tried on the charges of failing to report a case of contagious disease and of issuing a false death certificate, found guilty of both offenses as charged, and fined \$250.

Buffalo.

General Vaccination Urged.—Dr. W. D. Green, the health commissioner, has advised general vaccination in those not successfully vaccinated within four years. Smallpox is prevalent in Rochester, Cleveland and Detroit, and because of the interchange of traffic and lack of quarantine between these places it is but a question of time before another visitation of smallpox may be expected in Buffalo. The facilities for caring for such cases in this city are a disgrace to any civilized community, and the Board of Councilmen are menacing the health of the city by their delay in the selection of a proper site for the new quarantine hospital, for which a \$50,000 bonded indebtedness has been authorized.

OHIO.

Long in Practice.—Dr. Charles L. W. Wilgohs, Akron, the oldest practitioner in the state, celebrated his ninety-ninth birthday anniversary November 20. He was in active practice until a year ago.

New Akron Hospital.—The cornerstone of the new Akron City Hospital was laid with appropriate ceremonies, November 23. The building, which will cost about \$60,000, will stand as a monument to the generosity of Messrs. O. C. Barber and George T. Perkins. At the annual meeting of the staff, November 18, Dr. William C. Jacobs was elected president, Dr. Louis S. Sweitzer, vice-president, and Dr. Harry D. Todd, secretary.

Alleged Malpractice.—In the case of Mary H. Kimple against Dr. Moses D. Rabenoyich, Toledo, a verdict was returned for the defendant, November 26.—Dr. James A. Duncan, Toledo, is the defendant in a suit brought by George E. Howe, for \$10,000, for alleged improper treatment of a fractured leg.—Oscar Shanks has sued Dr. Alexander Smith, Pottersburg, for alleged failure to properly set a broken leg, and considers that he has been damaged to the extent of \$5550.—In the case of Matilda Tucker against Dr. William J. Gillette, Toledo, charged with having left a sponge in the abdominal cavity after an operation for appendicitis, the jury found for the plaintiff.

Cincinnati.

Poison Ward.—Two rooms at the City Hospital are to be fitted up especially for the treatment of acute poisoning cases.

Medical Library To Be Open Evenings.—At the regular monthly meeting of the trustees of the Cincinnati Hospital, it was decided that for the accommodation of the physicians of the city, the library will be kept open Tuesday, Wednesday, Thursday and Friday evenings. This is a concession that has long been earnestly sought by local physicians as the hospital boasts of the best medical library in the city.

New Post-Graduate School.—It was recently decided to establish a new clinic and post-graduate school, to be called the Cincinnati Polyclinic. A site is to be purchased on Seventh Street, between Main and Sycamore. The following staff of

officers was elected: President, Dr. Louis J. Krouse; vice-presidents, Drs. Adolph Morganstern and Edwin S. Ricketts; secretary, Dr. Oscar W. Stark; treasurer, Dr. William C. Harris, and director of clinics, Dr. Travis Carroll.

The Bureau of Infectious and Contagious Diseases of the Cincinnati Health Department makes the following report for the week ended November 14: Total number of cases 78, with 16 deaths; typhoid fever seems to be somewhat on the decrease, only 12 cases having been reported during the week; diphtheria and scarlet fever are on the increase, 15 and 20 cases respectively having been reported; smallpox still continues with 3 cases for the week; other diseases scattering.

PENNSYLVANIA.

St. John's Hospital.—Allegheny recently received a new addition comprising 4 wards and 29 private rooms. The cost was about \$33,000.

Banquet at Pittsburg.—Dr. John B. Deaver was the guest of honor and made the principal address at the eleventh annual banquet of the Western Pennsylvania Medical Society, Pittsburg, November 25.

Hospital Endowment Fund.—Bryn Mawr Hospital has received from the estate of Mrs. Esther F. Wistar, Philadelphia, \$12,505.88 in cash and property valued at \$76,000, which is to constitute the Dr. Mifflin Wistar Memorial Fund.

Bequest to Allentown Hospital.—By the will of John E. Leutz, Allentown, a bequest of \$1000 is made to the endowment fund of the Allentown Hospital. Should the children of deceased die without heirs one-third of his estate is to go to the same institution.

Personal.—Drs. Walter E. Miller and Paris Shoaff, New Castle, were seriously injured in a runaway accident, November 21.—Dr. J. Ellis Glasgow, Cresson, has been made senior resident physician of Mercy Hospital, Pittsburg. He is succeeded by Dr. J. Stein of Philadelphia.

In Memory of Dr. Davis.—At its meeting, November 18, in Oil City, the Venango County Medical Society adopted resolutions of regret for the death of its late member, Dr. Francis F. Davis, and many of his associates paid personal tributes to his qualities as a man and as a physician.

Anatomical Board Complains.—The State Anatomical Board of Pennsylvania makes complaint that the pathologists of the Philadelphia Hospital and Almshouse are using about half of the dead bodies of that institution and that this renders it difficult to supply sufficient material to the medical colleges of the state. The pathologists affirm that they are not using more material than is necessary.

Physician Exonerated.—After a trial lasting two and a half days, Dr. Frank R. Gerhart, of Union, was acquitted of malpractice in the suit brought against him by Daniel Shirey. Judge Ementrout told the jury that there was no evidence presented that there was any lack of skill on Dr. Gerhart's part, and that the experts agreed that nothing could be done to save the leg, and that such being the case, it would be an outrage to find a verdict for the plaintiff. The jury was told that if there were such verdicts no physician would be safe in the practice of his profession.

Philadelphia.

The Philadelphia Pediatric Society is to be addressed, December 9, by Dr. A. Jacobi of New York. A reception will be held after the meeting at the Hotel Stentor in Dr. Jacobi's honor.

The New Hospital Site.—The probability of the purchase by the city of swamp lands for hospital purposes has led to the call for a special meeting of the county medical society to discuss resolutions protesting against such purchase.

Appropriation for Hospital.—The Bureau of Charities, in its estimate of expenses for next year, asked the finance committee of City Councils for \$1,250,000 to buy sites and erect buildings for an almshouse, hospital for the insane poor and municipal hospital.

Dr. Judson Daland entertained the members of the Daland Medical Society of the University of Pennsylvania at his residence, November 17, to the number of about 200. Before going to supper the guests listened to an address by Dr. Henry Beates, Jr., president of the State Board of Medical Examiners.

WISCONSIN.

Personal.—Dr. Peter H. Jobse, Milwaukee, started for Vienna, Berlin and Paris November 27.—Dr. William F. Becker has been appointed a trustee of the Milwaukee Hospital for the Insane.

Charged with Fraudulent Practice.—Charles A. Clark, alias Henry Spencer of Rosewell, Marathon County, was placed under arrest, November 25, charged with fraudulently obtaining his certificate to practice. It is charged by the police that Spencer, for a consideration of \$50, got his diploma from Dr. Charles A. Clark, Center Lake, Antrim County, Mich.

Against Tuberculosis.—The State Board of Health, in its annual report to be made to Gov. La Follette in January next, will recommend that an appropriation be made for the establishment of a state hospital for the treatment of tuberculosis. It will also urge the legislature to appropriate a large enough fund to carry on the work of stamping out this disease, which, it is believed, can be done if the outdoor treatment, now in vogue in the east, is introduced.

Entrance Examination Requirement.—According to accounts in the Wisconsin newspapers, as a result of the investigation by the State Board of Medical Examiners, all students who apply in the future for admission either to the Milwaukee Medical College or the Wisconsin College of Physicians and Surgeons must pass an examination conducted by a representative of the board. The charges against the College of Physicians and Surgeons were finally withdrawn.

GENERAL.

Government Feeding Test.—The test of various preservatives and their effects on food, health and nutrition is in progress in Washington. Professor W. H. Wiley, chief of the bureau of chemistry of the agricultural department, has begun a series of experiments on twelve young men in government employ, as mentioned editorially in THE JOURNAL of August 9, page 318.

Monument for Virchow.—The German committee in charge of the celebration in honor of Virchow's eightieth birthday is collecting funds to a monument to his memory. The undersigned will receive and acknowledge contributions: Drs. Frank Billings, president of the American Medical Association, 100 State Street, Chicago; Thomas D. Coleman, 505 Greene Street, Augusta, Ga.; A. Jacobi, 19 East 47th Street, New York City; W. W. Keen, 1729 Chestnut Street, Philadelphia; and Wm. H. Welch, 935 St. Paul Street, Baltimore.

Army Medical Staff Praised.—The annual report of the Secretary of War, Hon. Elihu Root, praises the Army Medical Corps and recommends that Major Walter Reed (since deceased) be appointed assistant surgeon-general, with the rank of colonel, and that Major W. C. Gorgas be made deputy surgeon-general, with the rank of lieutenant colonel. Concerning the abolishment of the army canteen, the secretary says:

I am convinced that the general effect of prohibiting the use of beer and light wines within the limited area of the army post is to lead the enlisted men to go out of the post, to frequent vile resorts which cluster in the neighborhood, to drink bad whisky to excess and to associate intimately with abandoned men and more abandoned women, and that the operation of the law is to increase drunkenness, disease of the most loathsome kind, insubordination, desertion and moral and physical degeneration.

Nobel Prizes for Finsen and Ross.—As THE JOURNAL announced last week, the Nobel research prize of \$40,000 has been awarded to Major Donald Ross of the Liverpool School of Tropical Medicine in recognition of his investigations into the mosquito malaria theory. The prize for natural science and chemistry is awarded to Dr. Emil Fischer, University of Berlin, and the prize for physics and medicine is to be divided between Drs. Arrhenius of the Stockholm High School and Finsen of Copenhagen. The formal announcements are to be made in Stockholm, Sweden, December 10, the anniversary of Dr. Nobel's death. The prizes will be presented by King Oscar of Sweden. They are the second of the series provided in the will of Alfred Nobel, the Swedish scientist and inventor of dynamite. He left a fund of about \$5,000,000 in the hands of trustees, the income of which was to be paid each year for the five most notable achievements in the interests of humanity. This income now amounts to the sum of \$200,000, making it possible to pay prizes of \$40,000 each to those considered most deserving. The two prizes not yet awarded are for the most notable achievement in literature and for the greatest service in behalf of international peace and world disarmament.

CANADA.

St. John, N. B., Vital Statistics.—During the year ended October 31, deaths in St. John due to diseases of the circulatory organs numbered 92; of the respiratory organs, 89; total from all causes, 714.

Ottawa Vital Statistics.—There were 1173 deaths at Ottawa during the past twelve months, as compared with 1273

for the preceding official year. The death rate per 1000, estimating the population of Ottawa at 60,000, was 19.5 as compared with 21.1 for the previous year.

Personal.—Dr. T. A. Starkey, whose appointment as professor of hygiene in the faculty of medicine at McGill University we recently mentioned, arrived in Montreal last week from London.

New Chemical Society at McGill.—A new and much-needed chemical society was recently formed at McGill University, with the following officers: President, Dr. Harrington; vice-president, Dr. Ruttan; secretary, Dr. Evans; executive, Drs. Walker and Barnes. Meetings of the society will be held fortnightly, on alternate weeks with the physical society. This is the first year that such a society has existed at McGill.

Toronto Barbers Want Hygienic Methods.—Representatives of the Toronto barbers waited on the Provincial Board of Health at its meeting last week and discussed with them a report which was presented to the board by Dr. J. J. Cassidy of Toronto. The subject will be introduced at the next meeting of the Toronto Barbers' Association with the idea of initiating definite action along the lines indicated in Dr. Cassidy's report.

Ontario Vaccination Act Out of Date.—The regular quarterly meeting of the Ontario Board of Health was held in Toronto last week. Dr. P. H. Bryce, secretary, presented his annual report, recommending that the old vaccination act of 1863 be repealed and a more simple act passed in its stead. He suggested that the new act provide for a monthly report of all children born in a municipality by municipal clerks to the district medical health officers who would be appointed public vaccinators required to proffer free vaccination to such children at their homes. It should provide also that no children be permitted to enter educational institutions until they presented certificates of vaccination.

FOREIGN.

German Congress Postponed.—On account of the International Medical Congress at Madrid, the German Congress of Internal Medicine, usually held each April, will not convene again until April, 1904.

Unveiling of Bust of Westphal.—A portrait bust of Karl Westphal, for many years chief of the insane and neurologic service at the Charité, Berlin, was unveiled, November 8, with appropriate ceremonies. The bust stands in front of the new psychiatric clinic, and the principal address was delivered by Westphal's successor, Professor Jolly.

Antivivisectionists in Germany.—The German Anti-Cruelty to Animals Society recently brought suit against Dr. Vogt, a well-known neurologist at Berlin, for unwarranted vivisection. The suit was dismissed by the authorities as unfounded. Some of the results of Vogt's valuable experimental research have been mentioned in THE JOURNAL.

Large French Army Mortality.—General Andre, French minister of war, said it was a grave question how to combat tuberculosis in the Army. Typhoid fever is also responsible for many deaths. The average annual deaths numbered 2174, while they numbered only 741 in the German Army. Statistics showed that the French Army since the treaty of Frankfurt had lost 99,000 men from disease, and the German Army 13,000.

Practice Not Transferable in Germany.—A physician sold his practice to another and sued for the \$475 agreed on, which the buyer had failed to pay. The courts at Braunschweig, where the transaction occurred, dismissed the case, claiming that a medical practice is not a marketable commodity, and that a transaction involving its sale is unworthy of the profession and contrary to the best interests of the community.

Warning Against Tetanus from Gelatin.—A local medical society in Germany recently sent a circular to all the druggists in its district warning them that gelatin derived from animals that had died from tetanus was liable to cause tetanus in those injected with it. The value of gelatin as a hemostatic was emphasized, and the fact that sterilization is unable to free it from the toxic action of the virus. The only means of prophylaxis is that the gelatin should be made from animals positively exempt from tetanus.

Students' Number of Progres Medical of Paris.—The issue of this weekly for November 8 contains detailed information in regard to the medical faculties, colleges, etc., the prizes offered, the theses presented, the hospitals and clinics, hours, etc., and every detail to furnish what aims to be a complete medical guide to France and the French-speaking countries. The various scientific societies that have any relation to medi-

cine are also described, and the regulations for admission to the colleges, for license to practice, etc.

Opening for Physicians in Paraguay.—A German physician residing at Asuncion, Paraguay, in a letter to a colleague in Germany, published in the *Allg. Med. Ct.-Ztg.*, states that skilful physicians are sought after in Paraguay and high fees paid. It is difficult to obtain permission to practice as the clique of charlatans intrigue against the admission of foreign physicians. But this obstacle once surmounted the physician finds appreciation. There are comparatively no restrictions to practicing outside of the cities, and yet the field is a good one.

Personal.—The new public hospital at Schöneberg, a suburb of Berlin, has been placed in charge of Professor Albert Landerer of Stuttgart. He has long been director of the Olga Hospital at the latter place. Von Düring's achievements in combating venereal disease in Turkey have been described in these columns. He has been appointed chief of the official polyclinic for cutaneous and venereal diseases at Kiel.—Dr. Helene Stelzner has been appointed voluntary medical attendant at the Charité, Berlin. She passed the "Staats-Examen" at Halle *summa cum laude*.

German Cancer Research Committee.—The regions in Germany in which cancer was found to be most prevalent according to the recent collective inquiry, are being thoroughly investigated by the central committee. Additional circulars of inquiry have been sent to the physicians practicing there and physicians are to be sent from the central office to study the conditions on the spot. Von Leyden, Kirchner and Wutzdorf are at the head of the cancer research committee and are striving to make it the nucleus for an international committee for the centralization of data on the subject of malignant neoplasms.

Open-Air Sanatorium for Tuberculous Children.—The German Red Cross Society maintained last summer a fresh-air sanatorium for children in a pine grove not far from Berlin, similar to the day resorts which have proved so successful for tuberculous men and women. The results were so strikingly beneficial that six of these open-air sanatoriums are to be arranged encircling Vienna, and the children recognized by the medical school inspectors as anemic or debilitated are to be transferred there. Arrangements are being planned for 1000 children from the start, with medical attendance and kindergarten teachers in charge.

The International Sanitary Conference of the American Republics was in session in Washington this week. The governments of Mexico, Cuba, Chile, Costa Rica, Salvador, Honduras, and the United States were represented. The conference is the outgrowth of the international meeting held a year ago in the City of Mexico. Quarantine and sanitation matters generally were discussed. Measures to improve the existing systems will be considered by an international sanitary bureau before the assembling of the next annual conference. Dr. Walter Wyman, surgeon general of the United States Public Health and Marine-Hospital Service, was elected president, and Dr. Arthur R. Reynolds of Chicago secretary.

Organization in Holland.—The Netherlands Medical Association has completed its fifty-second year of existence exclusively occupied with scientific questions. Its journal has always restricted its contents to strictly scientific communications. The younger members hope to see it transformed to take cognizance of the material interests of the profession, and devote a portion of its space to the questions of organization for material benefits. A letter from Amsterdam in the *Wiener klin. Rundschau* of November 2, describes these conditions and states that energetic social-political measures are required to stem the downward trend of the economic interests of the profession. A special meeting has been called to discuss these questions.

The Mexican Public Health Department.—As early as 1628 the medical men in the Spanish colonies secured the organization of a board of health, and the present "Consejo Superior de Salubridad" of Mexico proudly dates its birth from this beginning. The last *Boletín* contains a historical review of the work accomplished during the centuries, and cites ancient regulations which show the farsighted policy of its members from the earliest times. The fact that its resolutions and advice were not always heeded does not detract from the merit of the council. Since Diaz has been president the council has played an extremely important part in the general progress accomplished. In 1891 it drew up a sanitary code which was officially adopted by the authorities. Dr. Eduardo Liceaga has been the president of the council for a number of years, and

has been a familiar figure at all the sanitary and similar congresses of the last decades in America.

Berlin School Hygiene Association.—Professor Baginsky presided at the first public evening meeting of this new society. The first address was by Hoffa, on the "Origin of Spinal Curvature During School Life," illustrated by drawings and casts. He remarked that "sitting is fatiguing under all circumstances," and that the slight expressions of fatigue in the attitude gradually become fixed habits in children and entail actual curvature. The proportion of scoliotic children constantly increases with the higher classes. Girls are more inclined to it than boys, and in the girls' seminaries more than 50 per cent. of the scholars are affected. He recommended seats with "the minus distance," and appealed most earnestly for frequent gymnastic exercises at brief intervals. Lehmann spoke on "Inheritance and Experience," observing that modern dramatic art has made such a bugaboo of heredity that there is a tendency among teachers to ascribe altogether too much importance to it in their professional work.

LONDON LETTER.

Pathogenic Bacillus Coli in Ice Creams.—In reference to an outbreak of ice-cream poisoning which has recently been described in *THE JOURNAL* (page 1060), Dr. Klein made an important bacteriologic report. He drew attention to the fact that in several outbreaks of acute gastroenteritis due to the consumption of particular meats the variety of bacillus coli known as bacillus Gärtner had been proved to be the real cause of the disease; but there had been other similar outbreaks of disease in which not the bacillus Gärtner, but other varieties of bacillus coli were the cause; he referred to the Carlisle outbreak (pork pie) described in the reports of the medical officer of the Local Government Board for 1889, and to the Portsmouth outbreak (meat pie) described in the same reports for 1890. Quite recently Dr. Klein has found in certain samples of ice creams a highly virulent variety of bacillus coli which was certainly not bacillus Gärtner. Some of these ice creams were made in shops which were under suspicion of having sold ice cream that caused acute gastroenteritis in a number of boys. The virulent bacillus coli isolated in its action on rodent animals by injection and after ingestion in its cultural and morphologic characters, was described and demonstrated by specimens. The virulent bacillus coli was met with in a succession of samples made on different days by the same maker under very unsanitary conditions as to locality, manipulation and storage. As soon as these unsanitary conditions became amended the ice creams proved harmless to animals. This is an experimental confirmation of the correctness of the recently-passed law as to the manufacture and sale of ice creams.

Cancer Research Fund.

The executive committee have selected Dr. E. F. Bashford, assistant to Professor Sir Thomas R. Fraser of Edinburgh from among the numerous applicants for the post of superintendent of cancer research. Dr. Bashford, who has recently been engaged in research work in Professor Ehrlich's laboratory of Frankfurt, and who is acquainted with the cancer research work now going on in Germany, will at once enter on his duties. A special sub-committee on statistics is being formed, and the general organization of the scheme is now being proceeded with as far as the funds will permit. The amount collected as yet is only about \$225,000, which is considerably less than the sum necessary to give full effect to all the objects of the scheme.

Colonial Medical Reports.

"Selections from Colonial Medical Reports for 1900 and 1901" has been issued recently. The volume deals largely with tropical medicine. Dr. Thomson of Hong Kong confirms the fact that on the presence of the anopheles depends the number of cases of fever in a given locality. The total destruction of such a large family as the mosquito seems almost impossible, though in individual cases much good may be done. Dr. Harvey of Bermuda discusses the yellow fever epidemics in that colony in 1856 and 1864, and points out several facts which could well be explained by the theory of the dissemination of the disease by mosquitoes. He thinks that probably the culex mosquito has been introduced to Bermuda by ships or travelers, and the reason that there is no malaria is that the anopheles mosquito has not yet been imported. The extermination of mosquitoes in Bermuda, where every house has its tank for drinking water, he thinks impossible, especially as the female culex mosquito will use the smallest collection of stagnant rain water for breeding purposes. Beri-beri receives much attention in several of the reports. It is one of the

chief causes of death among the Malays. Dr. W. L. Braddon, state surgeon Negri Sembilan, is of opinion that it is due to the eating of rice, which has been rendered toxic. Dr. Gimlette, acting residency surgeon of Peang, referring to the observation in Japan that dogs may contract beri-beri, states that at Benton, where beri-beri was very prevalent in 1900, ducks apparently succumbed to the disease in large numbers. In the Dutch East Indies the disease has apparently been found in hens. Another disease, the causation of which is still disputed, is yaws. It has extended considerably in Trinidad and Tobago, in spite of the efforts to combat it. Dr. Lovell, the surgeon-general, thinks that local house infection plays an important part in its dissemination. He advocates the removal of patients and the disinfection of the contaminated area. The report on syphilis from Basutoland shows that the natives there show little manifestation of the disease at its commencement. "The hard chancre is very rarely seen, yet let a single case of syphilis be introduced into a previously clean village, and in a few months a large percentage of the inhabitants, especially children, will be found with secondary eruption." It is noteworthy that in Europeans who contract the disease from natives the classical features are always observed. Dr. Otto Galgey, in reporting from St. Lucia on the filaria sanguinis hominis, refers to Dr. Lowe's discovery that filaria is directly inoculated into men by the bite of the mosquito.

Correspondence.

A Higher Standard of Entrance to Ohio Medical Schools.

COLUMBUS, OHIO, Dec. 1, 1902.

To the Editor:—We have read with approval your editorial entitled "A Higher Standard of Entrance to Ohio Medical Schools" on page 1326 of *THE JOURNAL* of Nov. 22, 1902, but we wish to call your attention to an error which we find in the last paragraph of this editorial. The paragraph referred to reads as follows:

It is not to be expected that any new methods will be perfect from the first, and the present defects in the Ohio system, the lack of uniformity of examinations by the different examiners, for example, are only the temporary imperfections of a new machine that will be remedied by time and use.

We beg to take exceptions to the statement that there is a lack of uniformity in the examinations for entrance to medical colleges in the State of Ohio. The questions used in the examinations in the four cities, Cincinnati, Cleveland, Columbus and Toledo, are exactly the same, are given out at exactly the same hour and on the same day, so that we regard these examinations as nearly uniform as can be made unless the entire examination should be conducted in one city and under the supervision of one man.

The four examiners meet together previous to each examination and agree among themselves as to the standard of grading. We also desire to call your attention to section 4403-c of the law regulating the practice of medicine and surgery in the State of Ohio; also to the enclosed list of questions which were given out at all the entrance examinations in September of this year.

In justice to the Ohio Board, we would request that the error be corrected. Very sincerely,

N. R. COLEMAN, President.

FRANK WINDERS, Secretary.

[We are glad to publish the above communication. The objectionable paragraph in our editorial referred to was based on criticisms made by gentlemen in Ohio. While in that state recently we took occasion to learn how the profession liked the new law and its working, by interviewing several interested parties. With practical unanimity all agreed that the change was a good one, although it was hurting the colleges. The only criticism made was that the examination in the four cities was not uniform. None of those interviewed seemed to know that the same questions were asked at all the examinations, and that they were, therefore, uniform. Three or four gentlemen were very insistent that this supposed lack of uniformity was a most grievous affair. An intimation was made, for instance, that the standard of examination for entrance into the Cincinnati medical schools was very much higher than for the schools in certain other cities. On the other hand, a gentle-

man from Columbus assured the writer that the standard in Cincinnati was much lower than in Columbus, that in the latter city being, in fact, higher than in either of the other three cities. We are especially glad to be able to convey the information to the Ohio profession that there is a uniformity in these entrance examinations in their state. We wish that those who are interested in medical education, as well as those who have any interest in medical legislation, would look into the Ohio law. There are now three states—Ohio, New York and Pennsylvania—which have taken from the medical colleges the control of the entrance requirement.—Ed.]

A Simple Chloroform Dropper.

WASHINGTON, D. C., Nov. 27, 1902.

To the Editor:—To obtain a dropper which will drop and not flow in a small stream or fail to drop except by violent agitation, I have adopted the following plan:

A piece of toothpick or a match stem is inserted between the cork and neck of the bottle, the rapidity of the flow being controlled by the tightness of the cork or the size of the splinter. The toothpick is then broken off close to the cork. It does not become occluded, and the number of drops each minute are about the same. It fills every requirement that the more expensive dropper does, and in some respects is far superior. Not infrequently we are compelled to intrust the anesthetic to an inexperienced person, and we have a little less concern if we know that the chloroform can be given drop by drop only, and by no possible chance can be poured on in larger quantities.

Further, we are often called on to administer anesthesia most unexpectedly; in those instances, this impromptu dropper is a friend in need. It may be given from the original container and without notching the cork, as is sometimes done, thus subsequently losing chloroform by leakage and evaporation.

I do not claim originality for this method, but saw it first used by Dr. W. P. Carr of this city, and have since used it frequently with great satisfaction. CHAS. S. WHITE.

State Boards of Registration.

Schedule of Minimum Educational Requirements of Medical Colleges, Adopted by the Colorado State Board of Medical Examiners, October 7, 1902.

Dr. S. D. Van Meter, secretary, sends us the following schedule:

On and after Jan. 1, 1903, no medical school will be considered in "good standing" which does not, as a minimum, require the following schedule:

CONDITIONS OF ADMISSION TO LECTURE COURSES.

1. Creditable certificates of good moral character signed by two physicians of good standing in the state in which the applicant last resided.
2. As evidence of preliminary education, as a minimum requirement, a diploma or certificate of graduation from a high school, or a certificate signed by a principal of a regularly organized high school, or by the examiner of the faculty of a recognized literary university, or by the state superintendent of public schools, of having matriculation in all the several branches of a four years' high school course. The applicant shall not be conducted by any member of the college.

Each applicant for a state certificate to present documentary evidence of his preliminary education, together with his medical diploma, when applying for license on a diploma dated after Jan. 1, 1903.

The conditions above set forth will govern in the case of all persons admitted to the freshman year of a medical college in "good standing" on or after Jan. 1, 1903.

ADVANCED STANDING.

Applicants holding the degree of A.B. or B.S., or an equivalent degree, from a regularly established college of arts or science, which requires an attendance of three or more years as an essential to graduation, may be given credit for work done in the branches of the medical curriculum of the first year and may be advanced to the sophomore year of a four years' medical course, on condition that they comply with the entrance requirements of this board and that they subsequently complete the work of the freshman year if not already completed, and that the work already taken shall not be below the standard required by this board.

The same conditions may be allowed on the same conditions to dentistry degree from a recognized college of medicine, or documentary evidence of having completed in a reputable university or college of arts or science the major part of the work usually embraced in the curriculum of the freshman course of a recognized medical school.

No such advanced standing shall be allowed until after the applicant shall have either graduated as indicated or performed the work specified above, and not until three months after the completion of said work.

The above requirements for advanced standing will govern in the case of all persons admitted to the sophomore year of a medical college on or after Jan. 1, 1903, and may be made operative prior to that time.

Graduates of medical colleges recognized at any time by the Colorado State Board of Medical Examiners may be admitted to any class without examination. Students of said colleges who possess certificates of attendance and of successful examinations can enter without examination the term immediately following that previously attended. The student shall be required to pass an examination in all branches in which he has been found deficient. Students who have attended one or more full terms in colleges not fully recognized by this board may be granted advanced standing in accordance with such attendance, on complying with the entrance requirements set forth in the conditions of admission to lecture courses, and passing all examinations and performing all laboratory work of the classes below that which they enter, providing that the work already done conforms to the requirements of this board.

Graduates or students of colleges to which no recognition is given by the Colorado State Board of Medical Examiners can be granted no advanced standing whatever.

LENGTH, NUMBER AND CHARACTER OF COURSES OF LECTURES.

The college shall have a four years' course of instruction, consisting of four terms, extending over a period of four calendar years, and the minimum time between the commencement of the work of the freshman year and the ending of the work of the senior year, on which all students are required to be in attendance, shall be not less than forty months. No two terms begun on or after Jan. 1, 1903, shall commence and end within any consecutive sixteen months.

The time occupied in each regular term begun on or after Jan. 1, 1903, shall be not less than seven months or thirty weeks, and each such term shall consist of not less than eight hundred hours of work.

The branches of medicine to be included in the course of instruction shall be at least as follows: (1) Anatomy, (2) physiology, (3) chemistry, (4) materia medica and therapeutics, (5) theory and practice of medicine, including ophthalmology, otology, dermatology and neurology, (6) pathology and bacteriology, (7) surgery, including orthopedic surgery, (8) obstetrics, (9) gynecology, (10) hygiene, (11) medical jurisprudence (forensic medicine).

ATTENDANCE.

Regular attendance during the entire lecture courses shall be required, allowance being made only for absences occasioned by the sickness of the student or his immediate family, such absence not to exceed 20 per centum of the course.

DISSECTIONS, CLINICS AND HOSPITAL ATTENDANCE.

1. Each student must have dissected at least the lateral half of a human cadaver.
2. He shall have received clinical and hospital instruction throughout at least two annual terms.

INSTRUCTION.

The college must have a sufficient and competent corps of instructors, and facilities for teaching, dissections, ambulatory and hospital clinics such as obtain in the majority of medical colleges in the United States.

GRADUATION.

No student shall be graduated by any medical college in "good standing" with the Colorado State Board of Medical Examiners who has not completed four full terms of lectures, as prescribed by the rules of the said board (certain persons to whom advanced standing is allowed excepted), and has completed the requirements of the said college, as set forth in the conditions of the college, and has completed in the diploma is granted, a continuous course of lectures in the senior year of at least seven months in duration.

FURTHER CONDITIONS OR RECOGNITION OF MEDICAL COLLEGES.

1. Only regularly conducted and legally chartered medical colleges which conform to the conditions of admission to lecture courses, the course and period of study, the number, character and length of lecture terms, the duration of attendance on hospital and clinical instruction, as set forth in the schedule of minimum requirements adopted by the Colorado State Board of Medical Examiners, and the other requirements of a medical education which obtain as a condition of the established medical colleges in this state, shall be considered medical institutions for the purpose of the Act to Regulate the Practice of Medicine in the State of Colorado.
2. No college shall be considered in "good standing" until it has established its claim to such standing by an active existence of not less than four years, and then only on compliance with the terms of the first condition. *Provided*, that colleges which after a personal investigation made by a committee of the Colorado State Board of Medical Examiners are shown to comply with the schedule of minimum requirements and to possess a sufficient and competent corps of instructors, and the necessary facilities for teaching, may, at the discretion of the board, be granted full recognition during the first year of existence.
3. All medical colleges in "good standing" with the Colorado State Board of Medical Examiners will be required to publish in their annual announcements or catalogues a complete list of all matriculates and a separate list of all graduates of the session or year immediately preceding.
4. No medical college will be considered in "good standing" with the Colorado State Board of Medical Examiners which publishes in its annual announcement or catalogue any misrepresentations regarding the curriculum of the college, or the facilities for instruction or the number of students matriculating or graduated.

All rules and regulations adopted by the Colorado State Board of Medical Examiners will stand repealed as of Dec. 31, 1902.

District of Columbia Report.—Dr. Wm. C. Woodward, secretary of the Board of Medical Supervisors, of the District of

Columbia, reports the examination held at Washington, October 9, as follows: Number of subjects examined in, 17; total number of written questions, 80; percentage required to pass, 75; partly oral and partly written examination; total number examined, 11; passed, 10; failed, 1.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

NO NOTICE TAKEN OF UNSIGNED COMMUNICATIONS.

In spite of the notice at the head of this department we are daily receiving unsigned communications, many of which we should be glad to notice. We repeat that every unsigned letter received is consigned to the waste basket, without reading, if the fact that it is not signed is discovered before it is read. We do not print the names of writers if requested not to do so.

FOWLER'S POSITION.

MATAGORDA, TEX., Nov. 10, 1902.

To the Editor:—Will you please inform me in your query column as to what is meant by Fowler's position in appendicitis?

S. A. FOOTE, M.D.

ANS.—We presume our correspondent refers to the upright position in which the patient is placed after abdominal operations; a position which, we believe, was first advocated by Dr. G. R. Fowler of Brooklyn, some two years ago. Instead of being put in bed in the horizontal position, the patient is placed in the "sitting up" position, so that the trunk is perpendicular. The object of the position is to facilitate drainage into the pelvis since septic processes confined to the lower part of the peritoneal cavity are less liable to result seriously than would be the case higher up, or in the diaphragmatic region. This position is adopted by some surgeons after all abdominal operations.

REMEDIES FOR OBESITY.

NEWARK, N. J., Nov. 29, 1902.

To the Editor:—On p. 1269 of THE JOURNAL I notice that you refer an inquirer to Von Noorden's article and forget all about the work of our American investigator, Heinrich Stern, on this subject. You yourself published an essay of Dr. Stern's on this subject which in my opinion is classic. I am very much astonished that you should have allowed such an omission.

W. O. BAILEY.

ANS.—We regret the oversight, and thank our correspondent for calling attention to it. Dr. Stern's article is one of the most important that has been written on the subject. It appeared in THE JOURNAL of February 15, p. 447, of vol. xxxviii.

Marriages.

W. J. REDFIELD, M.D., Union, Neb., to Miss Roe of Omaha, Neb., November 19.

FRANK J. POWERS, M.D., to Miss Annie Theresa Grogan, both of Baltimore, November 19.

EDWARD H. BOUNDS, M.D., to Miss Ellene Drescher, both of Hannibal, Mo., November 19.

THOMAS F. STALEY, M.D., to Miss Sue Sayers Reynolds, both of Bristol, Va., November 18.

FRANCIS J. WELSH, M.D., to Miss Minnie Doremus, both of Kalamazoo, Mich., November 26.

BAKER FORE, M.D., Marion, S. C., to Miss Aline Cole of North Birmingham, Ala., November 15.

EDWARD V. MILHOLLAND, M.D., to Miss Ella Cecilia Gordon, both of Baltimore, November 19.

SAMUEL B. ALISON, M.D., Carlowville, Ala., to Miss Emma Lide of Richmond, Ala., November 27.

GEORGE EDWARD KINCAID, M.D., Clinton, Iowa, to Miss Gra Gould of St. Louis, Mo., November 24.

ALFRED LARGE, M.D., Great Barrington, Mass., to Miss Sabir E. Archibald of Darien, Conn., November 15.

FRANK H. MUNKWITZ, M.D., to Miss Hedwig Josephir Elser, both of Milwaukee, Wis., December 3.

JOHN ARCHIBALD BROWN, M.D., Kankakee, Ill., to Viol Henriette Palmer, M.D., Chicago, November 27.

ABRAHAM D. MURPHEY, M.D., Cincinnati, Ohio, to Miss Kat May Anderson of Owensboro, Ky., November 20.

WILLIAM B. PIGG, M.D., South McAlester, I. T., to Miss Florence Rosser of Fayetteville, Ark., November 14.

NEWTON S. BACON, M.D., North Cambridge, Mass., to Miss Anne Rogers Dustin of Gloucester, Mass., November 6.

FRANCIS ALBERT BAKEMAN, M.D., Franklin, N. H., to Miss Mabel Pierson Johnson of Winthrop, Mass., November 12.

JOHN S. PINE, M.D., of Frederick County, Va., to Miss Ell M. White of Lebanon Church, Shenandoah County, Va., November 19.

Deaths.

Thomas H. Price, M.D. Jefferson Medical College, Philadelphia, 1876, died at the Episcopal Hospital, Philadelphia November 22, from sepsis consequent on a splinter wound of the hand, after an illness of two weeks, aged 54. He was a member of the Philadelphia County Medical Society and of the Philadelphia Emergency Corps.

Frederick Eugene Potter, M.D. University of Vermont, Burlington, 1860, who served throughout the Civil War, and for ten years thereafter as a surgeon in the U. S. Navy, and then practiced in Portsmouth, N. H., died at his home in that city, November 18, after a lingering illness, aged 63.

J. A. Ferguson, M.D., Ottawa, the hero of the disastrous fire at the Laurentian Sanitarium at Ste. Agathe des Monts, Quebec, some months ago, died at the home of his parents, November 19, aged 29. It is only a few weeks since he was presented with the Humane Society's medal.

William T. Garwood, M.D. Cooper Medical College, San Francisco, 1864, for nearly 40 years a practitioner of that city, died, November 21, from paralysis, after an illness of two years, aged 65.

Lee B. Windham, Jr., M.D. Medical College of Alabama, Mobile, 1900, died, November 14, at Stafford, Ariz., where he had gone for his health from his home in Stone, Ala., a few weeks before.

Edwin G. Granville, M.D. Kansas City Hospital College of Medicine, 1885, died at his home in that city, November 24, from spinal disease, after an illness of twelve years, aged 59.

Z. R. Millard, M.D. Medical College of Evansville, Ind., 1846, one of the oldest practitioners of Southern Illinois, died at his home in Thackery, Hamilton County, November 19.

Philip P. Duval, M.D. University of Virginia, Charlottesville, 1846, died at his home in Richmond, November 20, from pneumonia, after an illness of eight days, aged 75.

George A. Hillsman, M.D. Jefferson Medical College, Philadelphia, 1888, died at his home in Livermore, Ky., November 19, from pneumonia, after a short illness, aged 40.

Henry J. Cushing, M.D. Harvard University Medical School, Boston, 1868, died at his home in Merrimac, Mass., November 18, from angina pectoris, aged 65.

Charles H. Shaffer, M.D. Western Reserve University, Cleveland, Ohio, 1882, died at his home in Elizabeth, Pa., November 21, after a brief illness, aged 44.

Charles C. Sprague, M.D. Rush Medical College, Chicago, 1869, died suddenly at his home in Hull, Ill., November 19, from heart disease, aged 67.

A. C. Brasel, M.D. Tennessee Medical College, Knoxville, 1901, died at his home in Petros, Tenn., November 21, after an illness of six weeks.

John M. Cunningham, M.D. University of Louisville, Ky., 1891, died at Marlinton, W. Va., November 20.

Deaths Abroad.

Dr. Wulffert of Berlin, founder and president of the "Society of Abstinent Physicians," died November 5.—Dr. F. Fuhr, professor of surgery at Giessen, died in that city, November 3. His works include articles on the enucleation of the thyroid

gland, surgical treatment of intestinal occlusion, also a historical study of goiter in antiquity.—Dr. Joaquim de Magalhães, the oldest physician in Brazil, died at Baepén, October 10, aged 93. He was also prominent as a member of the legislature.

Dr. E. Liebendoerfer, formerly a medical missionary to India, died at Stuttgart in his fiftieth year. He served as a missionary for some years and then studied medicine, returning for ten years' service as a medical missionary, until compelled to leave India by failing health. He was the principal founder of the German Society for Medical Missions, and the fine hospital now approaching completion at Cameroon is mainly due to his efforts.

Sensai Nagayo, M.D., court counselor and president of the Central Sanitary Board, Japan, the father of sanitation in that country, died at his home in Tokyo, recently, aged 63.

Dr. Monere, mayor of Palaiseau, aged 95, who commenced the practice of medicine in 1830. He was a member of the *Conseil général* of the Seine for fifty years.

Book Notices.

A TEXT-BOOK OF SURGERY. By Dr. Hermann Tilmanns, Professor in the University at Leipzig. Translated from the Seventh German Edition by Benjamin T. Tilton, M.D., Instructor in Surgery, Cornell University, and John Rogers, M.D., Instructor in Surgery, Cornell University. Edited by Lewis A. Stimson, M.D., Professor of Surgery, Cornell University. Volume I. The Principles of Surgery and Surgical Pathology. With 516 Illustrations. Cloth. Pp. 841. Price, \$5.00 per volume. New York: D. Appleton & Co. 1901.

Tilmanns' Surgery has been a standard work in Germany for many years, and the great popularity of the work has been well deserved. The English translation of the seventh edition by Drs. Tilton and Rogers places in the hands of those unable to read German a work of great value, and the labor of the translators will certainly be appreciated. The amount of space devoted to the subjects in this first volume is not only an indication of their importance, but also of the very thorough manner in which they are covered. It is unfortunate that such German works are only translated after another edition has appeared, or is about to appear in the original, so that the translation is always one edition behind; but notwithstanding this fact the translation of Tilmanns' Surgery is a very valuable addition to English surgical literature.

THE STORY OF A LIVING TEMPLE. A Study of the Human Body. By Frederick M. Rossiter, B.S., M.D., and Mary Henry Rossiter, A.M. Cloth. Pp. 348. Price, \$1.00 net. Chicago, New York and Toronto: Fleming H. Revell Co. 1902.

This book is intended for, and will be read with profit by, children no matter of what age. It is the story of the living temple—the body—told in simple language so that the youngest who can read will understand. It is the child's text-book of anatomy and physiology, yet free from even a hint of a technical word. A religious and moral sentiment pervades the work, and no occasion is lost to call attention to the harmful habits in living, in eating and in drinking, to the harm in fast eating, improper foods, tobacco, alcohol, tea, coffee, etc. While facts are sometimes sacrificed to theory, and slight exaggeration is occasionally indulged in, on the whole the book is one to be highly commended. It is written in an entertaining, simple, yet dignified style, so that the reading of it by the average boy or girl will be not only profitable, but a pleasure.

HUMAN EMBRYOLOGY AND MORPHOLOGY. By Arthur Keith, M.D. (Aberd.), F.R.C.S. (Eng.), Lecturer on Anatomy, London Hospital Medical College. Illustrated. Pp. 324. Price, \$4.50. London: Edward Arnold. 1902. New York: Longmans, Green & Co., Agts.

The necessity of a knowledge of human embryology is constantly becoming more apparent, particularly to the surgeon, as many pathologic conditions are to be comprehended only by a thorough understanding of the evolutionary development of the various organs and tissues of the body. In the present volume not only is the embryology clearly described, but where possible particular mention is made of the effects of arrest of development and the surgical importance of vestigia atavisms, etc. The arrangement of the matter seems rather peculiar, as the work begins with a description of the development of the face and neck, with the accessory cavities and sense organs, before anything is said of the various layers of the embryo from which the various organs and parts are developed. It would seem more rational to begin at the beginning, but not-

withstanding the confusion in the arrangement of the matter, the work is a very deserving one.

THE TREATMENT OF FRACTURES. By Chas. L. Scudder, M.D., Assistant in Clinical and Operative Surgery, Harvard Medical School. Third Edition. Revised and Enlarged. Octavo, 480 Pages. With 100 Illustrations. Polished Buckram. Price, \$4.50 net. W. B. Saunders & Co. 1902.

The first edition of this book appeared in 1900, the second in 1901, and the third in 1902, a record which in itself is a sufficient recommendation of the excellence of the work. As the former editions were reviewed in these columns, it is only necessary to state that in this, the third edition, much new matter has been added. Deserving of particular mention is the chapter on gunshot fractures of the long bones, based on recent experiences in the late wars. Several uncommon fractures have also been illustrated and described, which add to the value of the work. The same excellence in point of illustration, paper and print has been maintained in this as in the former editions.

TEXT-BOOK OF MEDICAL JURISPRUDENCE AND TOXICOLOGY. By John J. Reese, M.D., Late Professor of Medical Jurisprudence and Toxicology in the University of Pennsylvania. Revised by Henry Leffmann, A.M., M.D., Toxicology in the Woman's Medical College. Pp. 660. Price, \$3.00 net. Philadelphia: P. Blakiston's Son & Co. 1902.

This edition of Reese's medical jurisprudence has been revised, bringing it up to date, noticing more modern procedures, agents, etc., which need consideration under this head. In other respects it is largely the same as its predecessors and will probably hold its place in the literature of this important department of law and medicine.

KIRK'S HANDBOOK OF PHYSIOLOGY. Revised by William H. Rockwell, Jr., M.D., and Charles L. Dana, A.M., M.D., Professor of Diseases of the Nervous System, Cornell University Medical College, New York. Seventeenth American Edition. With Upwards of 500 Illustrations, Including Many in Colors. Cloth. Pp. 854. Price, \$3.00. New York: Wm. Wood & Co. 1902.

The rapid appearance of new editions of Kirk's Physiology shows in what favor it is held. In the present one the chief changes are found in the articles relating to physiologic chemistry, the very marked advances in this department having required them. In other respects the work is much the same as the previous edition.

A BRIEF OF NECROSCOPY AND ITS MEDICOLEGAL RELATIONS. By Gustav Schmidt, M.D. Pp. 186. Price, \$1.00 net. New York and London: Funk and Wagnalls Company.

This is a pocket manual prepared to meet the special needs of a physician, lawyer and expert witness, produced in very compact form with leather binding, rounded edges, and one that will undoubtedly be largely used by lawyers and others who have to deal with the cases of autopsies, etc., in legal practice. It seems to be well arranged and fairly full, and the diagrams in the beginning will be an aid to the lay users of the work.

THE QUEEN SELF-REGULATING X-RAY TUBE. Paper. Pp. 35. Queen & Co., Inc., 110 Chestnut St., Philadelphia.

While this is only a trade catalogue it is deserving of mention in these columns from the fact that it contains illustrations showing in actual colors the appearance of x-ray tubes when operating under different conditions. These are unique and will be interesting to those using the x-ray machine.

Medical Organization.

OHIO.

When the Constitution and By-laws proposed for State Associations by the Committee on Organization of the American Medical Association were adopted by the Ohio State Medical Association at its Toledo meeting, on May 29, 1902, only a very few changes were made. The amendments made are as follows:

CONSTITUTION.

Article VIII, Section 1. Provision was made for four vice-presidents instead of three.

BY-LAWS.

Chapter IV, Section 2. The second word was made "shall" instead of "may," so that it is mandatory on the house of delegates to create councilor districts.

Same chapter, Section 13. The following phrase was added to the end of the section: "providing it shall not make void the verdict of a referendum."

Chapter VI, Section 2. The concluding words: "the council shall select one of the vice-presidents to succeed him", were struck out, and the following substituted: "the vice-presidents shall succeed him in the order of their election."

Chapter IX, Section 1. The annual dues were fixed for the present at \$1 instead of \$2.

Chapter X, Rules of Conduct, was reconstructed, and now reads as follows: "The ethical principles governing the members of the American Medical Association shall govern the conduct of the members of this association in their relations to each other and to the public."

A few other minor and unimportant verbal changes were made.

The reorganized association voted that until the next annual meeting the greater part of the routine work of the association, including especially the collection of the annual dues from members, should proceed as formerly under the old form of organization.

To the council of ten members was left the work of dividing the state into provisional councilor districts.

One councilor, Dr. Brooks F. Beebe, Cincinnati, has already assisted a number of the neighboring county societies, and as a result the Adams County Medical Society has adopted the new constitution and by-laws, and its secretary, Dr. O. T. Sproull of West Union, has forwarded to the secretary of the state association a full report on all the physicians in Adams County. This admirable piece of work clearly shows that the societies in counties not containing many large towns can very readily comply with the requirement in the state constitution that full lists of all physicians practicing in the county shall be made out each year, providing their secretaries are sufficiently interested.

Fayette County (Tenn.) Medical Society.

The physicians of Fayette County met at Somerville, November 12, for the purpose of organizing a county medical society. After a short explanation from Dr. Isaac A. McSwain, Paris, councilor for the district, and Dr. James A. Albright, Somerville, of the plan of organization, the following officers were elected: Dr. William B. Granberry, Somerville, president; Drs. David M. Morrow, Oakland, and M. M. Moody, Brinkley, vice-presidents, and Dr. A. B. Yancey, Jr., Williston, secretary and treasurer. Dr. James A. Albright was elected delegate to the Medical Association of the State of Tennessee.

Marquette County (Mich.) Medical Society.

This society, a branch of the Michigan State Medical Society, was organized, November 14, in Marquette. The new society will include in its jurisdiction Alger County, which has not a sufficient number of physicians for a separate organization. The constitution and by-laws recommended by the state medical society were adopted. Officers were elected as follows: President, Dr. John H. Andrus, Ishpeming; vice-president, Dr. Orrin G. Youngquist, Marquette; secretary, Dr. Harry J. Hornbogen, Marquette, and treasurer, Dr. George D. Beech, Champion.

Pulaski County (Ark.) Medical Society.

At a meeting, in Little Rock, November 17, the name of Little Rock Medical Society was changed to Pulaski County Medical Society. The constitution and by-laws as promulgated by the American Medical Association were adopted. The annual election of officers resulted as follows: Dr. Robert B. Christian, president; Dr. Anderson Watkins, vice-president; Dr. Charles C. Stephenson, secretary, and Dr. Rezin W. Lindsey, treasurer and librarian, all of Little Rock.

Williamson County (Tenn.) Medical Society.

A large number of physicians of Williamson County met at Franklin, November 15, to organize a county society. Dr. James P. Hanner, Franklin, was elected president; Dr. J. Blythe Core, Bethesda, vice-president, and Dr. Samuel White, Franklin, secretary. Dr. Worcester A. Bryan, Nashville, representing the Medical Association of the State of Tennessee, was present, and addressed the meeting and assisted in the organization of the society.

Kent County (Mich.) Medical Society.

About 100 physicians met in Grand Rapids, November 14, and formed the preliminary organization of the Kent County Medical Society, to be under the jurisdiction of the Michigan State Medical Society and the American Medical Association. Dr. Ralph H. Spencer was made temporary chairman and Dr. J. Harvey Innis, temporary secretary, both of Grand Rapids. Dr. Joseph B. Whinery, Grand Rapids, outlined the position of the proposed organization relative to its connection with the state and national bodies. A committee was appointed to pass on names and standing of the members who signed the following agreement: "We, the undersigned, agree to abide by the laws and regulations of the State Medical Society, to practice medicine without reference to school or pathy and to abide by the Code of Ethics as set forth by the American Medical Association. At the meeting for organization, November 21, Dr. Schuyler C. Graves was elected president; Dr. Richard R. Smith, vice-president; Dr. Francis J. Lee, secretary, and Dr. Leonidas E. Best, treasurer.

Medical Societies and the American Medical Association.

The following is quoted from the *Charlotte Medical Journal*:

One of the very vital and important subjects to the medical profession to-day is that of becoming more completely organized; that is, that there may be acquired a more nearly full membership of the societies of the United States in comparison to the whole number of physicians in active practice.

Such an organization of the profession in the Union would be of the greatest good to the largest number, in the truest meaning, of which the expression may be applied. Such an organization of the medical profession in the United States would be a power for the general good to our whole population. There would then be an influence which when exerted upon the legislative bodies for the purpose of securing sanitary measures or of prosecuting state medicine, would accomplish the object desired. Those means could thus be secured, which would add to the physical and moral welfare of every individual and of the whole population of the nation.

Besides, such an organization would be a vast post-graduate course to every physician in the land, serving not only as a continuation of the clinical atmosphere to the recent graduate, but a continuous school for the general practitioner, who strives to keep abreast of the real progress of the professional and scientific work in medicine. Dr. Nicholas Senn, in his presidential address in 1897, before the American Medical Association, said: "The medical societies, large and small, are the legitimate and proper post-graduate schools."

Through such means the profession takes a higher rank and each individual member thus becomes more proficient in his daily work. Through such physicians the patient is the gainer through the increased power which the physician possesses.

A united and organized profession will be able to more effectually study the great problems of scientific interest.

Every honorable medical practitioner in the United States who is eligible to membership in the medical society of his county should ally himself with the organized body and become an earnest, active member. He thus aids an association that will help him.

Every physician owes it as a duty to himself, to the society of the county in which he lives; he owes it to the whole organization as a profession of which he is a member; and he owes it especially to his patients who call him and confide in his ability to give them the recognized advantages which modern medical knowledge promises.

If a physician wishes to raise the query, does it justify him in becoming a member of and taking an active part in the work of a local medical society? let him look at the members of the medical profession throughout the United States, throughout the world, and observe where the great thinkers, the prominent and most successful practitioners, the leaders in the profession stand in regard to society work. He will observe that all of them are active in their local society work. There, all new thoughts or discussions are first presented. If such men are justified in expending time and means in the work of the medical society, the encouragement should apply to every prac-

itioner. Dr. J. B. Donaldson, in an address before the Medical Society of Washington County, Pennsylvania, quoted in *The Pennsylvania Medical Journal* for August, 1902, in an editorial, "Membership in County Societies," said: "To meet the medical men of our county is a treat that you can not afford to dispense with; it is a legitimate excuse to get 'out of the rut' and take a day off, that will do you good, socially as well as scientifically."

On the other hand, where do we find the charlatan? Isolation suits him best; he prefers secrecy for all of his methods of alluring the unwary. The more isolated a man becomes in his work the more narrow and egotistical he becomes in his views.

The American Medical Association in its reorganization plan, with the affiliated state and county societies, has in view the enlistment of every eligible regular practitioner in the Union. This should receive the thoughtful consideration of all practitioners who are not already members of a society, as well as encouragement of those who are already thus connected.

In 1903 the American Medical Association will meet at New Orleans. This will present again the opportunity for the practitioners of the southern states to be present at this scientific body, and to watch and take an interest in its proceedings. Let those who are eligible to membership in county societies secure such membership at once, that they may thus be in position to secure membership in the National Association and be entitled to attend the meeting next year.

Let as many physicians of the south as possible plan their arrangements that they may be present at the meeting and go prepared to help make it one of the greatest and most successful meetings in the history of the Association.

Association News.

The New Orleans Meeting.

To show that the profession of New Orleans is actively at work to make the next session of the American Medical Association a successful one, we copy the following from the December number of the *New Orleans Med. and Surg. Journal*:

The local Committee of Arrangements held a meeting, November 15, at the New Orleans Polyclinic, with the following members present: Dr. Isadore Dyer, Chairman; Drs. John Callan, Finance Committee; E. S. Lewis, Postoffice Committee; E. Souchon, Transportation Committee; Q. Kohnke, Exhibits; H. B. Gessner, Badges; R. Matas, Registration; J. F. Oechsner, Halls; F. A. Larue, Publication. Besides there were Dr. J. B. Guthrie, Secretary of the Committee, and Drs. C. J. Miller and E. Moss, representing other sub-committees.

The Chairman called attention to the purpose of the meeting as crystallizing the plans for the coming meeting of the Association. He stated that all of the committees had been organized and were well under way. He had communicated with each of the sections, and the secretaries of most of these had advised him of the probable attendance of each and the likely number for the banquet. Southern journals had been circularized with an idea of developing attendance through the Southern states.

Dr. Callan reported that the Finance Committee had held several meetings and had decided to issue a circular to the lay public, about December 1, appealing for contributions and stating the importance and character of the convention in May. The medical profession were to be circularized by the respective arrangements committees of the Association and of the State Society. It was decided to name a representative of the Association in each of the Congressional Districts in the state in order to derive contributions from that source. This plan had been agreed upon because of the proffer of assistance from country members who were anxious to share the honor and burden of the entertainment.

Dr. Gessner reported for the Committee on Badges that he had secured designs and prices from several manufacturers, which he submitted for the advice of the general committee. He had been unable to get any information from the 1902 committee, but he had secured a sample of the badge and souvenir of the St. Paul meeting. After some discussion it was decided that the committee be authorized to further investigate designs and to secure bids on 5200 badges at a price not to exceed

\$800. It was the sense of the committee that the souvenir should be suggestive of New Orleans, and at the same time of sufficient attractiveness to be taken away as a token of the city.

Dr. Oechsner, for the Committee on Halls, presented a very interesting report, showing the capacity in floor space and seating of the several available halls in the city and elaborating the plan of disposition of the several sections and bodies requiring accommodation. The work of this committee practically disposed of the plan of the meeting, and it was agreed that, unless strong reasons were advanced to the contrary, the meeting should be held in the section of the city including Tulane Hall, Tulane and Crescent theaters, Orleans Parish Medical Society, the Polyclinic, Medical College, Charity Hospital, Grunewald Hotel, as these afforded ample seating accommodations as well as space for exhibits, etc.

Dr. Parham reported that the Committee on New Membership had already begun circularizing neighboring states and that some 6000 eligibles would be reached within the next few weeks. Already a large number of members had been enlisted in Louisiana.

Dr. E. S. Lewis reported that the Postoffice Committee had conferred with the Postmaster of New Orleans, who had promised to supply alphabetically arranged boxes for the distribution of mail, which was to be delivered at the Bureau five times a day.

Dr. Martin reported, through Dr. Moss, for the Committee on Hotels and Boarding Houses, giving the hotel capacities and relating that a systematic bureau of information would be established regarding boarding houses, a list of which was already being made. At the recent bankers' convention this system had been used and had been found satisfactory.

Dr. Matas reported for the Committee on Registration that he had received full instructions from the treasurer of the Association, and that as soon as the location of this department had been determined, the work of his committee could be easily planned and executed.

At the adjournment of the committee meeting the members of the several sub-committees agreed to elaborate the work of each for a meeting to take place in January. Altogether it may be seen that the Arrangements Committee has the matter well in hand, and that early in the year the plans will be practically complete.

Societies.

COMING MEETING.

Western Surgical and Gynecological Association, St. Joseph, Mo. Dec. 29 and 30.

Philadelphia County Medical Society, North Branch.—This organization, at its recent annual meeting, elected Dr. H. Brooker Mills, chairman, and Dr. Frank C. Hammond, clerk.

Mercer County (Ky.) Medical Society.—Physicians of Mercer County met at Harrodsburg, November 18, and organized a county medical society, with Dr. Henry Plummer, Harrodsburg, president, and Dr. J. M. English, secretary.

Butler County (Mo.) Medical Society.—Ten of the fourteen physicians of Poplar Bluff met in that city, November 14, and organized this society, with Dr. Benjamin C. Jones, president; Dr. DeWitt F. Eskew, vice-president, and Dr. Gervaise L. Johnson, secretary.

South-Eastern Iowa Medical Society.—The thirty-second annual meeting of this society was held in Fairfield, November 20. Dr. George B. Little, Burlington, was elected president and Dr. Carl Stutsman, Burlington, secretary. The next meeting-place is to be Muscatine.

Penobscot County (Me.) Medical Society.—The annual meeting and banquet of this society were held in Bangor, November 18. Dr. Daniel McCann was elected president; Dr. Daniel A. Robinson, vice-president, and Dr. Bertram L. Bryant, secretary and treasurer, all of Bangor.

South Kansas Medical Society.—This society met for its annual session in Wichita, November 18 and 19. Dr. David W. Basham was elected president; Dr. Walter H. Graves, first vice-president; Dr. J. D. Clark, second vice-president; Dr. George K. Purves, secretary, and Dr. Arch D. Jones, treasurer, all of Wichita.

Jefferson County (Ohio) Medical Association.—The physicians of Jefferson County met at Steubenville, November 18, and reorganized this association, with Dr. Enoch Pearce, Steubenville, president; Dr. Hezekiah W. Nelson, Steubenville,

vice-president; Dr. J. Webster Collins, Toronto, secretary, and Dr. Joseph Robertson, Steubenville, treasurer.

New York State Association of Railway Surgeons.—The twelfth annual meeting of this association was held in New York City, November 21. The following officers were elected: President, Dr. Henry Flood, Elmira; vice-president, Dr. Charles J. C. Finn, Hempstead; secretary, Dr. George Chaffee, Brooklyn; and treasurer, Dr. James K. Stockwell, Oswego.

Middle Tennessee Medical Society.—At the annual meeting of this society held in Sparta, November 21, Dr. Rufus E. Fort, Nashville, was elected president; Dr. William B. Young, Bon Air, vice-president, and Dr. Leonard E. Ragsdale, Columbia, secretary and treasurer. Clarksville was selected as the next place of meeting.

CALIFORNIA ACADEMY OF MEDICINE.

Regular Meeting, held Nov. 25, 1902.

Report of a Case of Bubonic Plague.

DR. E. L. WEMPLE (by invitation) reported the case of a white man 33 years of age, married, a clerk in a furnishing store on Third street (near the business center, and a long distance from Chinatown), whom he found, October 27, suffering from backache, stiffness of the limbs, a feeling of anxiety and restlessness and great systemic depression. He refused all food, was nauseated, and had been vomiting. The bowels had moved several times in the three preceding days. The patient dated all his illness from the night of October 24. From this time on he felt a tumor in the right groin, the pain soon became intense, temperature 103.8; pulse, 96; respiration, 30. The tumor felt like a large mass of swollen glands in the femoral region; but as there was another above Poupart's ligament Dr. Wemple was in doubt as to its true nature, and advised that the man be taken to the hospital, where he would remove the mass. At 1:30 p. m. on the same day, October 27, he operated, and, cutting into the tumor, found it to be composed of large lymphatic glands, many of them hemorrhagic and not unlike placental tissue in appearance. There was an edematous condition of the skin and underlying structures from which oozed a glistening serum. He dissected out the glands from the pubic portion of the fascia lata, when he found that the swollen chain extended up into the pelvis. Suspecting that it might be a case of bubonic plague he had the patient quarantined. Smears from the glands showed *Bacillus pestis*, there being a diplococcus infection as well. The diagnosis was bacteriologically confirmed by the inoculation of a guinea-pig, by Dr. M. J. White of the United States Plague Laboratory.

The next day, October 28, the patient was removed to the City and County Hospital and quarantined. During this day 20 c. c. of Yersin's serum were given.

October 29, temperature 102.2 to 102.8; pulse 98 to 125; delirious; pain in back and abdomen; 20 c.c. of Yersin's serum given.

October 30; temperature 102.3 to 104; pulse 108 to 120; respiration 30 to 34; delirious; 40 c.c. of Yersin's serum at 4 p. m. At 11 p. m. 120 c.c. of serum intravenously in each arm; after this 80 c.c. more were given with no effect.

October 31, temperature 104.8; pulse 150; respiration 30; at 8 a. m. temperature 102.4; pulse 110; respiration 30. This latter was after 60 c.c. of serum had been injected and the bowels moved with calomel. Twelve, noon, temperature 104.4; pulse 130; respiration 32; 1/10 of a grain of strychnin was given from 2:30 a. m. to 8 a. m.; 1/10 of a grain of strychnin and 1/30 of atropin were given between 12 and 5 p. m. Unconscious, 5:30 p. m.; 5:50 p. m., temperature 108.4; pulse 170; respiration 43; 20 c.c. of serum given. Death 6:15 p. m.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, held Sept. 24, 1902.

The President, Dr. T. H. Fenton, in the Chair.

Intussusception in a Child.

DR. MORDECAI PRICE reported a case of "Intussusception in a Child Thirteen Years Old; Operation and Recovery." The patient had suffered with dysentery for five summers, and, when seen, had had dysentery for three months. There was

agonizing pain with emaciation. No positive diagnosis was made. On opening the abdomen, much of the ileum was found telescoped into the large bowel throughout almost the whole length of the latter. There was a large mass in the sigmoid at the brim of the pelvis. In the reduction of the condition the ileum was so badly injured that much of it was resected and the small bowel was inserted into the colon by use of a Murphy button five inches above the caput coli. The latter was amputated. Operation was done in July, 1902. Recovery was rapid and complete.

Dr. Price also briefly reported a case of polyhydramnios which he had recently delivered. Distention had been very great; there had been vomiting of blood and great emaciation. The pregnancy was 8½ months advanced. Partial dilatation of the cervix was accomplished with the hand, but the latter could not be inserted into the uterus, because of the intense intra-uterine pressure, until the membranes had been ruptured and a part of the amniotic fluid allowed to escape. The amniotic fluid measured 3½ gallons. Recovery was good.

Symposium on Typhoid Fever—1. Hemorrhage.

DR. R. G. CURTIN read a paper entitled "Hemorrhage in Typhoid Fever." The etiology is hard to explain. He thinks that the more profound the toxemia and the greater the blood changes the deeper will be the sloughing. He had never seen hemorrhage in a patient under 6 years; it is rare in children and when it occurs is rarely fatal.

It should be remembered that a patient may die without external signs of hemorrhage. The amount of blood loss may be estimated by the fall of temperature and depression. Those with most severe symptoms sometimes recover. The associated conditions most serious are renal disease, organic heart disease, hemophilia, tympanitic condition of the abdomen, obstinate diarrhea and vomiting. Treatment is believed to be usually more or less valuable. Following are some of the remedies advised: Ergot; turpentine externally and internally; oil of erigeron when the stomach will bear; mineral and vegetable astringents; ice externally and in the bowel, employed continuously; suprarenal extract the author has used with good effect; elevation of the foot of the bed; ligatures about the limbs. The speaker, in 1893, reported 17 cases with a mortality of 5. More recently he reported a series of 43 cases with a mortality of 23. The recent increase in mortality is ascribed to the cold water treatment. It is believed that the number of cases has also been increased. The effect of the sudden chilling is believed to congest the internal organs and thus increase the liability to hemorrhage. The speaker cited several cases in which he believed the cold bath or sponge to have been the immediate cause of hemorrhage.

2. Pain in Typhoid.

DR. H. B. ALLYN presented a paper: "Significance of Pain in Typhoid Fever." Pain was classified as extra-abdominal, due to hyperesthesia and hysteria, and as abdominal, due to intestinal colic, entero-colitis, cholecystitis and peritonitis either with or without perforation. The speaker dwelt on cholecystitis as a common complication, and believes that recrudescences often ascribed to indigestible food are really not infrequently due to this complication. Clinical cases were cited. Pain indicating perforation of the bowel is most serious. Tenderness and muscular rigidity are usual symptoms of this condition, but pain, often in the right lower quadrant of the abdomen, is the only constant symptom. Confidence was expressed in the value of the frequent skillful blood-counts regarding leucocytosis, especially as helping to diagnose complications. Pain and tenderness are not necessary accompaniments of typhoid fever, but should be regarded as danger signals.

3. Operation in Typhoid Perforation.

DR. R. G. LE CONTE advocated prompt operation following diagnosis of perforation. The peritonitis of typhoid perforation is much more rapid and widespread than that of appendicular perforation. Fatal result from operation may usually be attributed to one of two causes, namely, delay in operating, or surgical errors of judgment or technic. To prevent delay in operation, three things are essential: first, Osler's advice

must be followed and all our past cases of perforation carefully studied, that light may be thrown on the early diagnosis of this condition; second, in a hospital, consent for operation should habitually be obtained for all cases of typhoid fever; and third, the surgeon should be called at once in probable cases. It is too late when the diagnosis is made certain by signs of peritonitis.

Surgical errors of judgment and technic are discussed under four headings: 1. Shock; immediate operation is advised even in profound shock. 2. Incision is recommended in the right semilunar line as 85 to 90 per cent. of perforations will thus be exposed. 3. Treatment of the lesion. Where simple closure is possible, interrupted Lembert mattress sutures are advised. When closure is not practicable walling off the infected area by gauze is advocated. Resection of the bowel or formation of an artificial anus are methods for exceptional cases. Sometimes a single large opening may be plugged with a piece of omentum. 4. Peritoneal toilet and drainage. When peritoneal infection is limited to the right lower quadrant of the abdomen, it is recommended that the infected coils of intestine be brought outside of the abdomen and cleansed with salt solution and gauze sponges, while the cavity within is sponged dry without flushing, and then free drainage assured with gauze strips and a tube leading to the pelvis. If, however, the peritonitis is extensive or universal, a supplemental median incision should be made, permitting considerable evisceration and copious douching, followed by free drainage. The patient's head should be maintained elevated, so that the fluid may gravitate to the pelvis, the least absorbable part of the peritoneum and most readily drained. The fact was cited that the average typhoid patient stands a short operation well, but that prolonged operation is attended with grave risks. Therefore, the simplest and shortest surgical procedure that is consistent with recovery should always be employed.

4. Feeding in Typhoid.

DR. WM. EGBERT ROBERTSON believes that the dietetic management of typhoid fever has been given too little attention. Very few statistical reports dealing with large numbers of cases have been made. The laboratory work of Pawlow and his pupils in St. Petersburg is of importance. They showed that both a psychical and a chemical secretion of the digestive glands takes place and that the former actually stimulates the latter. So, by tempting the appetite, a variety of food can be given in an effort to stimulate the desire for food; for food taken willingly, or especially with pleasure, is more apt to be digested and assimilated than when a food repugnant to the patient is forced on him. A fairly large postmortem experience on the part of the speaker has shown him that, no matter what the diet, except milk, the small bowel always contains liquid feces only, and that formed material is found only in the colon. When milk alone is allowed, or when it constitutes the bulk of the food, it is often found in putty-like masses all along the alimentary canal. Even when milk is well taken and assimilated, the wasting and exhaustion are pronounced, while in those well fed, this condition is usually absent. In fact, in well-fed cases, the condition which gave the disease its name is almost totally wanting, and convalescence is short. Of course, we can not expect to shorten the febrile period, but the time of total disability can be materially shortened. We have no remedy for the disease, and all our efforts must be directed toward the dietetic and hygienic management.

While he would not advocate a full diet, the following can be administered, not only without fear of harm, but with beneficial results: Eggs, raw or cooked, cereals, bread and butter, salad, well-cooked spinach, potatoes, macaroni, soups, gelatin, jellies, custards, all beverages such as tea, coffee, chocolate, etc., ice cream, and chicken. On such a diet the patient is able to combat the wasting, the liability to complications is lessened, and convalescence is shortened. Of course, in gravely toxic cases and to the comatose, only liquid food, if any, can be given.

Discussion on Typhoid Fever.

DR. G. G. DAVIS referred to the possible independent onset of appendicitis in typhoid. A plea was made for the support of the surgeon by the physician in doing early operation in perforation.

DR. HOBART A. HARE said he could not conceive how any ordinary styptic remedies can reach the seat of hemorrhage. He is convinced that Nature is always the chief factor in the arrest of such hemorrhage. Monsel's salt enclosed in several layers of capsules, he believes the only possible efficient remedy of this class. Exceptions were taken to those who believe in assuming chances in operating when perforation can not be positively diagnosed. Cases were mentioned in which operation being refused, recovery showed either a walling off of infection, or that no perforation had occurred. Operation in such cases may have proved fatal. The speaker has seen patients early in typhoid with all the symptoms of appendicitis.

As to feeding, the speaker expressed himself in favor of a more liberal diet than is often used. He believes in excluding meats and meat broths because they are good culture media, but favors giving soft eggs and strained thin starches, with some starch digestive ferment.

DR. MORDECAI PRICE expressed belief in the easy differential diagnosis of appendicitis and typhoid fever. Gangrenous appendicitis is the only variety simulating typhoid fever and it is rapid in onset. He believes in the median incision in operating for perforation, and believes in washing the peritoneal cavity with plain water, not with salt solution.

DR. JOHN H. GIBSON urged early operation, because general peritonitis means fatality. Of 11 cases operated on at the Pennsylvania Hospital, 4 had recovered.

DR. B. F. STAHL favors granting the demand which typhoid patients make for a variety of food, giving especially meat foods or starches. He likes sterile meat broths, especially one made at 167 F. or less, to which hydrochloric acid is added. He advises the use of several of the limitless variety of ways of preparing milk.

DR. WM. L. RODMAN considers hemorrhage as a surgical condition. Following surgical principles, he believes in the intestinal injection of water at 110 to 115 F. This may control hemorrhage; it at least combats shock. Rarely, he believes, is there a spontaneous cure following perforation. Whereas by operation perhaps 25 per cent. can be saved. A certain parallelism was pointed out between the condition of typhoid perforation and gunshot wound of the intestines—the two conditions demanding similar treatment. The speaker coincides mostly with the views of Dr. Le Conte, except that he believes in flushing the infected peritoneum rather than wiping it out.

DRS. CURTIN, ALLYN, ROBERTSON and LE CONTE closed with very brief remarks, the latter explaining that, if, in operating for perforation, he finds general peritonitis, he flushes the cavity freely; if only a few coils of intestine are infected, having drawn such coils outside the abdomen, he flushes them, afterward returning them, and always providing for free drainage.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, held Nov. 17, 1902.

The President, Dr. Alexander Lambert, in the Chair.

Unscientific and Careless Prescribing; Secret and Proprietary Remedies.

DR. HARRY R. PURDY called attention to many common errors in prescribing, occurring even with physicians who were capable and well-informed on other matters. He could only account for this on the ground that our medical schools had neglected to give proper instruction in pharmacy and pharmacology. There had been some improvement, but there was still room for much more, the so-called courses in these branches being wholly inadequate for the needs of the modern physician. The speaker inveighed against the increasing tendency for physicians to do their own dispensing, claiming that it led to unscientific and undignified prescribing, and that many of the tablets employed contained inferior drugs or those which by reason of age had largely lost their potency. He characterized those physicians who prescribed patent medicines as self-confessed incompetents and violators of the Code of Ethics.

DISCUSSION.

DR. E. ELIOT HARRIS took issue with the author in the classing together of patent medicines and proprietary medicines,

maintaining that, at the present time, a patent medicine is one, the working formula of which has been filed with the patent office. This formula is not a fake, but will enable any competent pharmaceutical chemist to reproduce the medicine. Proprietary medicines are essentially secret preparations, although the manufacturers of some of them will state the ingredients, though refusing to divulge the particular mode of manufacture.

DR. FREDERICK HOLME WIGGIN reinforced the position taken by the last speaker, and called attention to the fact that the New York State Medical Association is making an honest effort to keep the advertising columns of its publications free from objectionable matter by living up to the distinctions just laid down. He has not found the tablet medicines inert or unreliable. They are certainly useful in that they enable the physician to properly control the prescribed medication.

DR. GEORGE D. STEWART saw no occasion to take a pessimistic view, while admitting the need of a more liberal education in pharmacology. The older physician, who had not had the advantage of such instruction, should narrow his materia medica down to a few drugs, the nature and actions of which he knew most thoroughly.

MR. THOMAS J. KEENAN, speaking for the pharmacists, said that the latter view with alarm the growing tendency among physicians to prescribe proprietary articles. That there is such a tendency was well shown by taking at random, as he had done, 50 prescriptions from the files of a drug store, for the year 1882, and a similar number for 1901. Of the first fifty, 48 were found to be for official preparations; of the second fifty, no less than 41 were for proprietary articles.

DR. JAMES J. WALSH gave a number of examples of the danger arising from recommending to the laity in an informal way various remedies.

DR. E. MAXER was disposed to think that the pharmacists themselves were largely to blame for the present attitude of the profession toward prescriptions; in any case, one should carefully distinguish between elegant and ethical pharmaceutical preparations and those made only for money-making.

DR. E. V. DELPHEY spoke at length of many well-known proprietary preparations, mentioning them by name, and pointing out how little they had to commend them to the careful and conscientious physician.

MR. JAMES TAYLOR LEWIS remarked that if the formula of a patent medicine on file in the patent office proved not to be the correct working formula of that medicine, the patent on the same was void.

The Venous Hum in Relation to Blood Count.

DR. C. N. B. CAMAC reported 22 cases of anemia, in 21 of which the cervical bruit was audible. He said that while it was generally assumed that this bruit arose from a diminution in the caliber of the vessel and the consequent formation of "a fluid vein," certain recent experiments of Potain gave renewed emphasis to the older theory based on the thinness of the blood. The cases observed by the author were divided into the following groups: 1. Those in which there was a cervical bruit and hemoglobin percentage of 90 or over. 2. Those in which this bruit was associated with a hemoglobin percentage of 75 to 90 per cent. 3. Those in which the bruit was present with a percentage of hemoglobin of less than 75, and 4, cases in which there was no cervical bruit, and the hemoglobin percentage was below 75. Of the 22 cases, 21 had the cervical bruit. There were 15 cases belonging to the first, 2 to the second and 6 to the third group.

CHICAGO MEDICAL SOCIETY.

Regular Meeting, held Nov. 19, 1902.

The President, Dr. Wm. A. Evans, in the Chair.

Case of Ventrofixation, Pregnancy, Inversion of the Uterus, Death and Autopsy.

DRS. WM. E. HOLLAND and BYRON ROBINSON presented jointly a case of ventrofixation, followed in two years by pregnancy. At full term there was a short normal labor and delivery. Death occurred three and a half hours postpartum. The autopsy revealed complete inversion of the uterus. The

uterine circulation was injected *in situ* with red lead, the uterus removed, and an x-ray of the specimen secured. The authors presented observations and deductions concerning the relation of the ventrofixation to inversion of the uterus.

DISCUSSION.

DR. CHARLES E. PADDOCK propounded the question: "Why is it we find so many cases of inversion of the uterus now, when there were so few formerly?" He believes it is due largely to a misunderstanding of the Credé treatment of the third stage of labor.

DR. RUDOLPH W. HOLMES said that some years ago he presented a paper on the "Etiology of Inversion of the Uterus." He collected at that time 830 cases, 75 per cent. of them being due to spontaneous causes; 25 per cent. were due to the Credé method and to traction on the cord. He thinks abdominal pressure is the direct cause of the inversion in the larger proportion of cases.

DR. A. McDERMID said he performed the operation of ventrofixation on a patient some three years and a half ago. In listening to the report, he thought it was believed atrophy had occurred, owing to the method of fixation adopted, and that the atrophic band had inverted the uterus. When the uterus is fixed by any method to the abdominal wall, the anterior wall of the uterus during gestation, not being allowed to expand, becomes thick and dense, while the posterior wall becomes attenuated, and he thinks it is rare that the posterior aspect of the fundus is so attenuated that it is liable to cause inversion. The speaker had used the modified method of fixation of Martin of this city.

DR. C. S. BACON said it is hardly fair to attribute the inversion to the ventrofixation, and gave his reasons for so thinking.

DR. FRANKLIN H. MARTIN described a method of ventrofixation which he had used in 173 cases. Of this number only 30 were women who could bear children, and of these 30, 2 had children within one year to two years, after the fixation had been made. These women went on to term, were confined in a normal manner, and made no complaint. In each of these cases he had examined the uterus afterward and found it suspended.

DR. C. W. BARRETT thinks that ventrosuspension or fixation should be reserved for those cases in whom pregnancy may not occur afterward. He believes the weight of clinical evidence is tending that way.

The Gravity of Bronchitis in Elderly Men and the Safety Valve Action of Relative Tricuspid Insufficiency.

DR. ROBERT H. BARCOCK reported a case and drew the following conclusions:

1. Bronchitis in elderly, although robust, men may readily become chronic. Presuming on their previously good health and vigor, they think they can easily throw off their colds, and hence are apt to ignore medical aid until after the bronchitis has become settled and obstinate.

2. The cardio-vascular degenerations so often present and unrecognized in elderly men increase the tendency of bronchitis to become chronic. This is because the stiffened arteries and chronic myocarditis, even though the heart remains potentially equal to the demands of everyday life, tends to the production of pulmonary and bronchial congestion, which, when bronchitis once sets in, renders it less amenable to ordinary treatment. Moreover, the physician who may, perchance, be consulted is apt to overlook the influence of cardio-vascular changes, and contents himself with prescribing expectorants, whereas he should at the same time lessen the congestion by a brisk calomel cathartic. He should also, in many cases, inhibit exercise and attention to business, that the heart may be relieved of unnecessary strain.

3. Another element of danger in the bronchitis of elderly men is pneumonia. In most cases the bronchitis predisposes to a pneumonia, which may develop after the lapse of weeks or months, as in the case narrated. There is, however, the possibility that the bronchitis, which sets in abruptly and severely, may be but an attendant or manifestation of pneumococcus infection, and may obscure the signs of pneumonia when this is lobular.

4. A fourth danger lies in the effect of the bronchitis on the heart. Chronic myocarditis develops so insidiously that one may not always be able to detect it, and can not foresee how little extra strain may be required to seriously impair its potential strength.

Even should pneumonia not ensue, the mechanical strain of the bronchitis, especially if it leads to atelectasis and emphysema, and of repeated violent attacks of coughing, is capable of seriously damaging the degenerated right ventricle, the dilatation of which aggravates the already existing congestion.

5. Should such dilatation lead to relative tricuspid insufficiency, this is not to be regarded as a sign of danger *per se*, since it is in reality a safety valve which for a time protects the ventricle from disastrous over-distention. The tricuspid regurgitation is a criterion of the degree of mechanical strain to which the ventricle is subjected.

6. Such safety valve action not only furnishes a brief respite to the patient from the death threatening him, but affords to the physician a little longer interval in which to battle for victory, while it, at the same time, indicates the necessity of relieving dangerous congestion by cathartics, possibly also venesection, and cardiac tonics.

Circular Insanity.

DR. RICHARD DEWEY reported a case of circular insanity which he had studied clinically, differentially and medicolegally, and which will be published in *THE JOURNAL* later.

Ankylostoma Duodenale.

DR. JOSEPH A. CAPPS reported a case of ankylostoma duodenale. He gave the life-history of the parasite, described the modes of infection, and demonstrated specimens illustrating different phases of development, and then discussed the diagnosis and treatment.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Acne.

Dr. Leredde, in *Rev. de Ther.*, recommends, in the treatment of the various forms of acne, and the lichens, employing methods that will produce exfoliation of the epidermis and the mucous layer with subsequent desquamation, which results in carrying off the pathologic products. To accomplish this purpose, he employs strong alkaline soaps, resorcin, salicylic acid and beta-naphthol in the following combinations:

R. Zinci oxidī	5iiss	10
Resorcini	3x	40
Adipis benzoin.	5i	30

M. Sig.: Apply to the face once a week after washing the face with soap and water; or:

R. Beta-naphthol	5iiss	10
Sulphuris precip.	5iiss	45
Saponis viridis	3vi	24
Petrolati	5vi	24

M. Sig.: Apply locally; or:

R. Acidi salicylici		
Beta-naphthol, āā	gr. lxxv	5
Resorcin	5iiss	10
Sulphuris		
Amyli, āā	5vi	24
Saponis viridis	5iv	16
Petrolati	5vi	24

M. Sig.: Apply locally.

Or, in the form of a lotion as follows:

R. Tinct. saponis viridis (20 per cent.)	3x	40
Resorcin	5i	4
Sulph. precip.	5iiss	10

M. Sig.: Apply locally once a day for three days.

The author states that the paste, whichever one is used, may be allowed to remain in place for fifteen minutes in the beginning, gradually increased to thirty-five minutes in order

to gauge the reactive power of the skin. The foregoing lotion may be applied, as stated, daily for a few days.

The resulting inflammatory reaction may be tempered by means of the following salve:

R. Zinci oxidī		
Petrolati, āā	5iiss	10
Adipis laurē	5ss	15

M. Sig.: Apply locally.

Dressing for Wounds, Especially Bullet Wounds.

Paul von Bruns, professor of surgery in Tübingen Univ., recommends in the treatment of wounds, especially bullet wounds, a salve containing xeroform, combined as follows:

R. Xeroform	5iiss	10
Mucil. acacie		
Glycerini, āā	5v	20

M. Sig.: Apply locally as a dressing, substituting iodoform and salicylic acid powders.

Xeroform is the tribromophenol of bismuth. It is an odorless, tasteless, yellowish-green powder, employed externally as an antiseptic surgical dressing.

Herpes Zoster.

The object of treatment in herpes zoster, according to an abstract in *Med. News*, is to cure the vesicles, to prevent the suppuration and to quiet the neuralgic pains. The following combinations are recommended for local application:

R. Acidi tannici	gr. vii	45
Olei olivæ	5v	20
Cera flavæ	5iiss	10
M. Ft. unguentum.		
M. Sig.: Apply locally; or:		
R. Acidi borici	gr. xl	265
Cocainæ hyd.	gr. viii	50
Petrolati	5vss	22

M. Sig.: To be applied locally.

If gangrene or suppuration should make its appearance, wet compresses should be applied, followed by powdering with iodol or iodoform.

For the pain one may employ morphin, chloral, belladonna and quinin hydrobromate.

The following is recommended by Shoemaker:

R. Ferri pyrophos.	gr. xxx	2
Acidi arsenosi	gr. i	06
Quin. sulph.	gr. xxx	2

M. Ft. pil. No. 30. Sig.: One pill three times a day; or:

R. Tinct. nucis vom.		
Tinct. gelsemii, āā	m. lxxv	5

M. Sig.: From five to ten drops four times a day.

Diphtheria.

Patterson, in *South. Med. Jour.*, recommends the following in the treatment of diphtheria:

R. Pot. chloratis	gr. xv	1
Acidi muriatici dil.	5i	4
Tinct. ferri chloridi	5iiss	6
Aq. destil.	5vi	180

M. Sig.: Two tablespoonfuls in water every hour for adults and proportionately less for children.

Dysmenorrhea.

The *Med. Press and Circular* states that the inefficacy of the treatment of dysmenorrhea is shown by the multiplicity of remedies recommended. The statement is made, however, that beneficial results have been obtained from the administration of thyroid extract in dysmenorrhea owing to the intimate relationship which exists between the utero-ovarian zone and the thyroid gland. It is stated that Dr. Stinson of San Francisco has been successful in 80 per cent. of his cases. He administers a grain of the dried extract three times a day for one or two days preceding the menstruation and doubles the dose during the period.

Fisher, in an abstract in *Amer. Med.*, calls attention to the intimate association between the genital apparatus and the thyroid gland. He states that occurrences which influence the genital tract, such as puberty, pregnancy, and uterine fibroids, very frequently cause enlargement of the thyroid gland. He

also notes that deficiency of the normal thyroid secretion is often accompanied by atrophic changes in the genital apparatus. Consequently, it seems from the foregoing statements that thyroid extract is deserving of a place in the treatment of dysmenorrhea.

Edema of the Glottis.

The following combination is recommended by *Le Prog. Méd.* in the treatment of edema of the glottis:

R. Aluminis	
Acidi tannici, āā	gr. lxxv 5
Ext. krameriae	3iiss 10
Aquæ, q. s. ad.	Oi 500

M. Sig.: To be sprayed into the throat by means of an atomizer five or six times a day.

Appendicitis.

T. R. Brunton, according to the *Med. News*, recommends the use of sodium salicylate and belladonna in large doses in the treatment of appendicitis. He recommends sodium salicylate in fifteen or twenty grain doses, alternating with ten or fifteen drops of the tincture of belladonna, every two hours for a limited number of doses. It is not wise to mix them because it is important to stop their administration just as soon as the symptoms of intolerance arise or at any rate to decrease the size of the dose.

Turpentine in Scarlet Fever.

Tobeitz, in an article on the pathology and treatment of scarlet fever, according to *Archiv f. Kinder.*, recommends the use of turpentine in this disease. He states that instead of its producing an inflammatory condition of the kidneys it cures albuminuria and prevents nephritis. He uses it in the form of an injection hypodermically, given in fifteen minim doses (1.00) injected into the outer aspects of the thigh, followed two days later by twenty drops given internally in capsule, on sugar or in the form of an emulsion.

Acute Alcoholism.

The insomnia and intense nervousness, according to an abstract in *Ther. Monthly*, which frequently accompany acute alcoholism, should be corrected by promoting free elimination from the bowels, skin and kidneys. A brisk laxative in the form of Hunyadi water, seidlitz powder or magnesium citrate should be given, also a turkish bath, if not too depressing. Sodium bromid should be preferably used as a sedative and hypnotic. The author does not favor the indiscriminate use of bromids, chiefly because of the danger of producing gastric disturbance.

A mixture similar to the following is recommended:

R. Chloralis hydratis	
Sodii bromidi, āā	gr. xv 1
Tinct. capsici	m. x 65
Aq. menth. pip.	3ss 15

M. Sig.: At one dose.

The author, however, prefers paraldehyd as a hypnotic combined as follows:

R. Paraldehyd	3ss-3i 2-4
Olei olivæ	3ss 15

M. Sig.: At one dose to produce sleep.

Paraldehyd is said to produce sound, refreshing sleep, with no depressant after-effects. Food should be withheld until the bowels move freely.

Chorea.

The following combinations are serviceable, according to Yeo's *Man. of Ther.*, in the treatment of chorea:

ZINC OXID.

R. Zinci oxidi	gr. iii-vi 20-40
Sacch. albi	gr. lxxv 5

M. Ft. chart. No. i. Sig.: One such powder three times a day; or:

SODIUM ARSENATE.

R. Sodii arsenatis	gr. iss 09
Acidi carbol.	m. iii 20
Aquæ destil.	3iiss 10

M. Ft. solutio. Sig.: Five minims as an initial dose and repeat, according to age.

ASAFETIDA.

R. Asafetida	
Ext. valerianæ	
Zinci oxidi	
Castori pulv., āā	gr. xx 1 30
Ext. belladonnæ	gr. ii 12

M. Ft. pil. No. xx. Sig.: One or two night and morning.

IRON AND ARSENIC.

R. Tinct. ferri chloridi	3ii 8
Liquoris arsenicalis	3iii 12
Glycerini	3i 30
Aquæ chloroformi q. s. ad.	3iv 120

M. Sig.: One small teaspoonful of water after food three times a day.

QUININ, IRON AND ARSENIC.

R. Ferri reducti	gr. i-iii 06-20
Quin. sulph.	gr. ii-v 12-30
Acidi arsenosi	gr. 1/50-1/30 0012-0020

M. Sig.: To be taken in pill or capsule three times a day.

Dr. Otto Maier, in *Ped.*, recommends the following in the treatment of chorea: Rest in bed, cold sponge baths twice a day, light nutritious diet, no excitement of any kind, and the following to be taken internally:

R. Pot. bromidi	3i 4
Sol. pot. arsenitis	3ii 8
Syr. simp.	3ss 15
Aq. fontis q. s. ad.	3iii 90

M. Sig.: One teaspoonful three times a day well diluted in water.

Acute Nephritis.

The following is recommended by *Le Nord Med.* in the treatment of acute nephritis:

Absolute rest in bed, the legs wrapped in cotton covered with oil silk; exclusive milk diet; a glass of milk and vichy water every two hours. Hot drinks to produce sweating, especially the infusion of juniper berries. Give saline purgatives to promote excretion by the intestine and the following to be taken internally:

R. Cinchonæ sulph.	gr. ii 12
Benzonaphthol	gr. v 30

M. Sig.: One such cachet to be taken three times a day

Medicolegal.

Property Not Damaged by Location of Pesthouse.—In the case of Barret vs. the City and County of Henderson, an action brought to recover damages for the alleged depreciation of certain property by the location of a pesthouse near same, the Court of Appeals of Kentucky affirms a judgment in favor of the city and county. On the trial it was proved by a number of witnesses that the value of the property was decreased by the location of the pesthouse fully \$20 to \$30 an acre. The city and county then introduced one witness, who said he had known the land all his life, and it was just as valuable then as it was before the pesthouse was built. Two other of their witnesses were of the same opinion, but another two thought the land had been damaged. The only question made on the appeal was, in substance, that the verdict in favor of the city and county was palpably against the evidence. The proof showed that the nearest pesthouse to the party's line was 474 feet from it, and something over 1,250 feet from his house. The other pesthouses were still further off. The proof also showed that the contagion of smallpox could not be carried through the air more than 100 or 200 feet. There was some proof that it might be carried further, but the great weight of the evidence was otherwise, and this was confirmed by the fact that no contagion had yet resulted from these pesthouses. Under these circumstances, all the court has to say is that a jury, selected as juries ordinarily are, when the facts were proven before them, were peculiarly qualified to pass on a question of this character; for as practical men they could form their own judgments on the facts, and the court does not think that it ought to disturb their finding.

Salary Only Recoverable by Health Officer.—As the Supreme Court of Mississippi describes it, the case of *Yandell vs. Madison County* was brought by a physician, as health officer of the county, to recover upon a *quantum meruit*, or as much as he deserved, namely, the sum of \$892, for medical services rendered to residents of that county. To the several counts, or different statements of his claim, three in number, all of like character, he attached a bill of particulars, containing about 93 items, one of which items, which will serve to illustrate all the others, was as follows: "1901, Jan. 14. To visit Jesse Samuel (smallpox), \$15.00." To his declaration, or entire pleading, a demurrer was sustained, when he filed an amended count in *quantum meruit* also, but for \$800. In the amended declaration no mention was made of the services performed, but it alleged that for the year 1900 his predecessor in office had received at the rate of \$500 per annum, which had been fixed at that sum by the board of supervisors, and that his (Yandell's) services were worth more than the services of his predecessor. His amended declaration further alleged that the board for the year 1901 had fixed the health officer's salary at \$100 per annum, but it made no use of that fact except to ignore it. In truth, all the counts ignored the fact that his compensation was a salary, to be fixed by the board, and sought to recover on a *quantum meruit* for special services to sick persons within the county. The court thinks that a demurrer was rightly sustained to all the counts, because the physician could claim against the county his salary only, whatever that might be; and for such recovery neither of his counts was a suitable pleading.

Skill Required of Physician—In Isolated Locality.—The Court of Appeals of Kentucky finds reversible error in certain instructions given the jury in the malpractice case of *Burke vs. Foster*, which the trial court decided in favor of the physician. The negligence charged was failure to discover and treat a dislocation of the arm at the shoulder joint. The parties lived in a somewhat isolated village, in a rural community, on the Kentucky river, but not on any railroad line. The number of physicians residing and practicing in that "vicinity" was not shown, but presumably they were not numerous. By the instructions referred to, the skill, attention, and prudence required of the physician were restricted to such as were exercised by "ordinarily skilful and prudent physicians and surgeons in that vicinity in treating a like injury." The Court of Appeals admits that it has held that a physician could not complain of such instructions, as, without saying more, they were as favorable to him as he was entitled to. It also says that there are some cases which have limited the physician's liabilities by this standard. Yet, so far as Kentucky is concerned, it is not aware of any reported case where it has approved of this doctrine. It says that it may be that in any given community—a rural one, sparsely inhabited—there may be only one or two physicians, and they may each be utterly incompetent, and be what is popularly termed a "quack." Should the law permit such a one to hold himself out as a member of this learned profession, and invite the confidence and reliance of those suffering from serious injuries and ailments, so as to engage his services, and then, though he is a mere bungler and an ignoramus, an empiric of the lowest degree, allow him to escape liability for his negligence and lack of skill on the plea that he and his associates in the profession in that community are all of a kind, and none of them have either sense, care or capacity? The mere statement of the proposition would seem to carry with it its answer. On the other hand, it must be recognized that the most efficient and talented in the profession generally, and very naturally, seek better and more lucrative fields for employment; that those living in a sparsely settled neighborhood will not have, in any probability, the experience, the opportunity for acquiring skill by practice in such cases, that comes to the practitioner of medicine and surgery in the city. It generally follows, then, that the practitioners in rural localities have not the same high degree of skill, knowledge or education that may be found in large cities and populous communities. As the physician engages to bring to bear on the case only such skill and care as is ordinarily practiced by others of the same profession in like situation, his liability should be measured by that standard.

Wherefore, the court thinks that the sounder rule is, not that the physician's skill and degree of attention should be measured by those of his community, but by such as is exercised generally by physicians of ordinary care and skill in similar communities. Furthermore, the court holds one of the instructions erroneous because it precluded a recovery, whatever the physician's negligence or lack of skill, if the result was as good as was usually obtained in like cases similarly situated. It says that it is known of all men that many cases of injury or illness are recovered from without any medical attention, while many others of the same kind do not recover, although apparently the best medical attention is given. What the proportions are might be impossible to determine. It is equally well known that two or more cases of apparent similarity, treated by the same treatment, and, indeed, by the same physician, may, and often do, have directly opposite results as to recovery. The court thinks, when a physician undertakes to give his attention, care, and skill to a given case of injury or disease, the patient is entitled to the chance for the better results that are supposed to come from such treatment, and as are recorded by the science of his profession to a proper treatment. That the patient might have died in spite of the treatment, or that "ordinarily" they did die in such cases (as formerly in cases of cholera, smallpox, etc.), is no excuse to the physician who neglects to give his patient the benefit of the chance involved in a proper treatment of his case. That no treatment would avail; or that ordinarily careful treatment would not, might be shown, if the case so warranted. In this case, the patient was entitled to an ordinarily careful and thorough examination of his injuries, such as the circumstances attending their infliction, the condition of the patient, and the surgeon's opportunities for proper examination suggested and allowed. If the dislocation was discoverable by such examination, and if the physician felt that because of lack of appliances or lack of experience he was unable to treat any peculiar feature of the injury, it was at least the right of the injured man to be apprised of his condition, that he might call in more skilled attention if he desired.

1 **Eye Strain.**—Ranney reports cases of mental failure, epilepsy, chorea, paralysis, deformity, monoplegia, diabetes, neuralgia, nervous prostration and wry neck cured by correcting eye muscle errors. He claims that each case was scientifically investigated, and while several of them justified the diagnosis of organic brain disease, complete relief by operative procedures and glasses showed the importance of eye strain in their causation. He thinks they would show to an unprejudiced mind the necessity of making careful ocular examinations in all such cases.

2 **Intestinal Diseases in Infants.**—Kerley and Hughes give the results of treatment of the out patients, which they find more amenable to drugs than has generally been held. Their methods are to discontinue milk in all cases of vomiting or diarrhea, regardless of the nature of the attack, whether mild or severe, and substitute a carbohydrate diet. They find that egg albumin water is dangerous as a milk substitute and also beef juice and other animal broths, which must be used sparingly. Every case of gastrointestinal disturbance, however slight, had the milk changed to barley water, one tablespoonful to a pint, and a little castor oil given in the intestinal cases, and calomel, 1/10 of a grain, was given every hour until six tenths of a grain had been given in cases of vomiting. The stomach was washed and if there was diarrhea, bismuth mixture given. They analyze cases and describe the methods of treatment, the root garden, milk regulation and supply, etc.

3 **Rubber Gloves.**—The use of rubber gloves is deprecated by Morris, who thinks that they interfere with the expedition of operation, abolish the sense of touch and render greater the danger of injury to the peritoneum and bacterial infection. He believes that the actual resistance of the patient can be better conveyed by the surgeon who works rapidly and with smaller incisions than is possible if he places an obstacle between the sense of touch and the object toward which that touch is directed.

6 **Ectopic Gestation.**—Starting with a detailed report of cases, Wells discusses the subject and concludes that recurrent ectopic gestation is not extremely rare, and may be expected in a large proportion of pregnancies that occur subsequent to a tubal implantation of the ovum. We are not justified in taking out the remaining and apparently normal tube at the first operation, but we should watch with unusual care the early progress of any subsequent pregnancy. Careful pathologic examination of specimens is desirable. The most frequent etio logic factor of abnormal implantation of the ovum is, he thinks, most probably a mild infection of the tube, causing change in its epithelial lining, increasing the time occupied in the passage of the fertilized ovum through the tube.

7 **Typhoid Fever.**—Nammack names the characteristic diagnostic signs of typhoid, giving in tabulated form the differential diagnosis from acute miliary tuberculosis and cerebro-spinal fever.

8 **Cortical Paralysis.**—Kahn reports a case of traumatic cortical paralysis with anesthesia of the whole paralyzed side of the trunk, which he thinks indicates that the center for

sensation of the trunk must be located in the same area as the motor function.

12. **Epilepsy.**—Park describes the surgical treatment of epilepsy rather more hopefully than some surgeons. His conclusions are given in the following:

1. Epilepsy is the last disease to which surgical measures should be indiscriminately applied. In judiciously selected cases, radical operations of various kinds suited to the individual needs of each case, have given far more satisfactory results than has non operative or medicinal treatment.

2. Every case must be studied as a problem by itself. The only general laws applying are those regarding the removal of peripheral or local foci of irritation and the destruction of paths of conduction which convey disturbing impulses. In each case we must decide as to the operative method by which we may best meet these indications.

3. In order to attain the best results patients should be seen early. It would be well to have every epileptic carefully studied by an accomplished surgeon who should review the case with a view to the possibility of surgical intervention.

4. Operation, when indicated and undertaken should be regarded as a last measure to be followed, and often preceded by others looking to a correction of all faults of diet, of elimination etc. Long continued attention to these matters is the price of eventual success.

5. In those cases in which the face, when the seizures can be controlled by the prompt use of amyl nitrite we may well consider the propriety of an excision of the cervical sympathetic.

13.—Wakefield's article will be reviewed when completed.

15 **Verbal Amnesia.**—In the case reported by Gordon the patient was able to repeat words suggested to her, but was not able to give them without help. The partial loss of memory for words interfered with correct reading and writing. It was not the idea, but the verbal image that was wanting. He thinks the lesion was probably due to softening, as shown by the conditions of the patient's arteries and aorta.

16 **Adeno Carcinoma of Male Breast.**—Two cases are reported by Hammond, both operated on successfully, the first patient dying later from apoplexy, and the latter now in perfect health. In both cases the histologic diagnosis was that of adenocarcinoma, though one might possibly have been called a sarcoma.

17 **Paraffin Prothesis.**—Allen calls attention to the possibility of a sequence of paraffin prothesis of saddle nose, paralysis of the muscular action of the wings of the nose causing impeded nasal respiration. He thinks this must be looked for whenever paraffin injections are made. He holds that this can in a great measure be prevented by firmly compressing the wings of the nose by an assistant placing a thumb in each nostril, making counter pressure on the outside with the index fingers, the pressure being maintained until the nose has been molded into its proper shape.

19 **Obsessions.**—These symptoms, which pass under the name of fixed ideas, imperative conceptions, phobias, etc., are reviewed by Diller, who describes the types and reports cases. No hard and fast rules can be given as to their treatment. It should be directed mainly against the conditions from which these arise, though in all cases it may be more or less symptomatic. In any case mental treatment must be first and be individual. The physical tone must be maintained and here the simpler rules of hygiene are to be considered as well as the use of hydrotherapy, massage and electricity. Vacations, rest, exercise, recreations, all come under this head and while the treatment by drugs is of least importance, it is well to give some simple remedy, such as tincture of nux vomica, etc., for its tonic and mental impression. As a rule, however, the simpler the drug treatment the better.

20 **The Terms Acute and Chronic.**—From a study of the subject, Smith offers the following definition.

Acute, as applied to a pathologic process, indicates of such a disease that it runs a fairly regular and limited course, such course being frequently, although not necessarily attended by severity of symptoms and the limitation being possibly in recovery.

Chronic may be applied in conditions presenting no definite duration, more or less irregularity in the presentation of symptoms, a variable severity of symptoms and ordinarily limited only by the death of the patient.

21 **Neurasthenia.**—The symptoms and treatment are described by Aikin. He advocates special attention to environment. The hospital or the trained nurse at home can make practical the systematic application of required measures, the use of the bath, graded for the individual regulated diet, ex

cluding as a general rule the salted meats and more indigestible vegetables, starches, bananas and strawberries, as well as sweets, coffee, tea and alcohol. Water should be copiously used, but not at meal time. The slow sipping of very hot water about one-half hour before each meal is often of benefit to the atonic stomach. Saline and lithia drinks assist in lessening fermentation in the alimentary canal. Hot broths and milk just at bed-time often help sleep. The patient should be encouraged but not too much indulged. If the home treatment is too lenient in this respect, a change is required. General faradization, hydrotherapy and massage are all useful. Drugs should be the last thing, but most neurologists use them. Among them, iron is of first importance. The alkalies are of great service, the glycoposphates of lime and soda are recommended. The fluid extracts of aqueous solutions (instead of tinctures, should be used to avoid the alcohol. If any gastric disturbance exists it should be treated. For hypnotics, trional and the bromids given in hot milk or broth are the most useful. Opium and its derivatives with alcohol in every form, are to be avoided. Constipation is best treated by gradually decreasing doses of salines with increased ingestion of water.

22. Sex Production.—Kolipinski has studied sex production, taking 192 families and dividing them according to types as to the first three births. The theory which he advocates is that the person of the greatest will-power will produce his own sex first; understanding by will-power, decision, determination and resolution. From his studies he finds that more males than females are born and that twins are more common among boys than girls, that older fathers produce more boys, and that wives older than their husbands produce more girls, which last he explains on his theory that the older person has the stronger will. Prostitutes give birth mostly to boys, which he also explains on the ground of their debilitated will-power. Jews have more boy children than their surrounding races. Finally, male drunkards produce boys. Whether this is on account of the chronic alcoholic poisoning of the fathers or whether it results from the cowed and miserable state of the mothers, is left unsettled.

23. Nasal Obstruction.—The importance of nasal obstruction is emphasized by Donovan, who enumerates the symptoms produced by mouth breathing, and he advises the general physician who meets many cases of hacking cough, hay fever, asthma, bronchitis, etc., to carefully examine the nose. He thinks many cases of neuralgias, conjunctivitis, keratitis, iritis, and lachrymal trouble are relieved by attention to the nasal mucous membrane. Attention must be given to the clothing and diet and each individual case considered. As regards operations, he says he favors them where required, but says the job you underdo may be corrected later, while the one you overdo can never be corrected. Unless one is absolutely sure that a portion should be removed, it is best to leave it alone.

24. Barber-Surgeons.—Taylor's address is an interesting historical summary of barber-surgeons as an institution of the past.

25. Tetanus.—Seven cases of tetanus are reported by Strong, with a discussion of the condition.

26. Miscarriage.—Some points of practical value in the diagnosis and treatment are noted by Friedman; the first is pelvic pain associated with uterine bleeding. The symptoms, however, often simulate those of bleeding extra-uterine pregnancy. He points out the differences, the tender mass at the side of the uterus and the discharge of decidua gravidatis without chorionic villi, and the disproportion between the severity of the pain and the size of the uterus, and between the blood lost and a pulse which indicates hemorrhage, also lack of the globular enlargement of pregnancy, the enlargement being longitudinal only. The question of threatened or inevitable miscarriage must remain always one of personal judgment in these cases. He suggests a plan of treatment to cover all cases: 1. Where there is a high temperature indicative of sepsis, or decided affection of the pulse rate by the bleeding, the uterus should be at once emptied. Careful attention should be directed to conservation of the ovum if neither of these conditions is present. If no part of the ovum is prolapsed, if the

patient's pulse is good in quality and less than 110 beats per minute, treatment should be expectant and the case may be seen only occasionally if in charge of a good nurse. The prognosis is generally good. If radical measures are decided on he would use the finger as a curette so as not to injure too much the uterine mucosa and possibly set up the foundation for a subsequent endometritis. If the finger can not be used, curette should be employed and in that case the uterine cavity should be thoroughly irrigated with 1/5000 sublimate solution or 1.5 to 2 per cent. formalin or sterile water, the quantity being important. He thinks that most women either through design or unwittingly, underestimate the duration of their pregnancy, and this is a matter of importance as regards the removal of the placental remains or the decidua serotina. A seven or nine weeks he has found that a small tufted piece of chorion remains attached to the uterine wall and causes persistent bleeding, consequently, in very early miscarriages, this immature placenta must be sought.

27. Axillary Carcinoma; Amputation Through Shoulder Joint.—In 1897 Roberts advocated, before the Philadelphia Academy of Surgery, disarticulation of the shoulder-joint as a routine method of treatment for all cases of secondary axillary carcinoma from mammary tumors. This is different from the suggestion to remove the heavy lymphoid arm in order to get rid of the weight. He did not operate in this manner until 1899, and he reports a case. He subsequently found that Dr. Herman Mynter published in the *Buffalo Medical Journal* an account of a case in which he disarticulated the arm as a preliminary step to the removal of the malignant mass in the axilla, secondary to breast cancer. The patient lived a year. What he emphasizes particularly is that this should be advocated as a routine measure in all cases of axillary cancer, secondary to malignant disease of the breast, and that the subclavian artery and vein should be ligated above the clavicle before the disarticulation is done. Then the arm should be cut off and the lymph nodes and other affected tissues removed. A flap from the outer aspect of the arm may be retained to cover the axilla and chest, if such integument be needed.

28. Hernia.—The statistics as to the mortality, etc., of the operative treatment of hernia are reviewed by Martin, who remarks that the operation he has himself employed is practically the Halsted operation, differing only in the fact that the internal oblique and transversalis muscles are not cut. His records show 116 cases of hernia, including inguinal, femoral and the umbilical varieties. He tabulates these, giving the details briefly in cases of death, which were exclusively confined to the strangulated cases, and reports in detail several cases of interest, including four of properitoneal or interstitial hernia, one of reduction en masse and one of bowel rupture. In all the cases which he has been able to trace there has not been a single recurrence. He used in all, excepting two cases, non-absorbable sutures of silk and silver wire. In the two cases in which absorbable sutures were used, kangaroo tendons were employed. They did well, but he has not found it necessary to continue the use of this material for sutures.

30. Exophthalmic Goiter.—The case reported by Potts was peculiar. An ankle clonus existed during the disease, disappearing as the patient improved, and there were also attacks of apparent unconsciousness, the more complete ones lasting considerable periods of time, occurring after undue exertion and followed by more active symptoms of the disease. He also notes that marked improvement ensued from the use of sodium phosphate, and correction of the disease of the nasal mucous membrane, and emphasizes the bearing of the latter on the case.

31. Tuberculosis.—Two hundred and fifty cases are discussed by Campbell, 129 males and 121 females; 60 per cent. of the males being benefited, and 50 per cent. of the females. The former included more in the first stage of the disease, in which the proportion benefited reached 92 per cent. A family history of tuberculosis seemed to have some effect on the prognosis. Only 53 per cent. of subjects with this were known to have been benefited, while the percentage was 59 benefited of those with good family history. In the 21 cases in which the disease had not existed longer than three months, 73 per cent.

were benefited. In the 84 in which it had lasted longer than three months and less than one year, 56 per cent. were benefited. Of those in the first stage of the disease, 92 per cent. were benefited, and only 1.37 per cent. have died. In the third stage only 13 per cent. were benefited and 62 per cent. died. Of the total number of cases 17 $\frac{3}{5}$ per cent. were cured, leaving no symptoms whatever of the former disease except a slight dulness in the former consolidated area, and diminution of vesicular murmur. Hemorrhage occurred in 38 per cent. of cases, 16 per cent. being cured and 32 per cent. improved. A slightly larger percentage of cases without hemorrhage were cured and improved, showing that hemorrhage slightly reduces the chance of recovery. He calls attention to the importance of those going to Colorado having sufficient means to support themselves for a while, until they are sufficiently well to take up some light employment. He also insists on the importance of sending patients in the early stages rather than waiting for the fuller development of the disease.

32. Neurasthenia.—Walker finds from a study of neurasthenic cases that occasionally psychic symptoms of organic insanity may be present, recognizing, of course, that the early symptoms of these forms of mental disease are those which we habitually regard as functional. He emphasizes in conclusion the following points: 1. Every case of neurasthenia presents mental symptoms in some form. The difference between neurasthenia and certain forms of mental disease is largely one of degree; fundamentally they are the same, a pathologic lowering of the psychic functions, having the same etiology, and so far as he has been able to ascertain, the same underlying pathology of nutritive change in nerve-cells. From this point of view the mental symptoms assume greater significance and in many cases we may anticipate a greater degree of defectiveness to follow, depending on duration and virulence of exciting causes, the peculiar nature of causal poisons and vulnerability of individual tissue, and when they are encountered in one of previously known mental weakness, instability or eccentricity, or, in one of insane ancestry, they should lead to energetic measures not only remedial and reconstructive, but tending to the ultimate regulation of the environment and conduct of the patient in order that more serious developments may be prevented.

43. Schleich Anesthesia.—The different forms of anesthetics and agents are noticed by Stone, who has used the Schleich solution in 666 operations, in 31 cases for long operations averaging 100 minutes to the operation. He gives certain anesthetic points, such as the muscular tone of the heart being the most important pre-anesthetic condition, the lymphatic habit the most dangerous. Securing the confidence of the patient is one of the most important duties of the anesthetist. The anesthetic should be given in a perfectly quiet room, never preceded by morphin, and care be taken that no artificial plate is left in the mouth. For chloroform the Esmarch mask is the best; the Stone mask is one of the best for ether and the Schleich solution. Begin slowly, never allow force used to restrain the patient, secure if possible profound surgical anesthesia before using the knife, and never observe the operation when giving the anesthetic. Watch the color of the face, lobe of the ear, also the pupil and temporal pulse. Train your ear so that it hears every breath without seeming to listen to the respiration. Add your anesthetic, whatever it may be, from the best dropper with constant uniform additions, the rapidity varying with the stage of the operation. Beware of a heart of feeble tone; use adrenalin or strychnia prior to anesthesia. In chloroform anesthesia beware of half-closed eyes. In the Schleich anesthesia only a fraction of patients with half-closed eyes give trouble. Keep the possibility of death on the table in mind. The normal pupil in good surgical anesthesia is well contracted and steady. A rapidly dilating pupil from a contracting one means imminent death. A pin-point pupil is indicative of a too profound anesthesia. Do not be alarmed by noisy respiration during rectal operations. Secure profound anesthesia before division of the sphincter ani, and, if using chloroform, remove the mask the moment the surgeon's fingers touch the anus for division. A deep inspiration of chloroform can easily kill: this precaution is not necessary with the

Schleich solution. Never forget that partial anesthesia, "just enough to keep them under," is most dangerous. Never forget that the safest anesthesia is surgical anesthesia, steadily maintained, and that the least quantity of anesthetic which will assure this is best. If you ever have trouble, keep your head and act promptly. If collapse takes place, or ashy pallor and cessation of pulse, give adrenalin and strychnia at once, lower the head, making rhythmic traction of the tongue every four seconds and artificial respiration if this fails. Death is nearly always due to unskillful administration—administration of an overdose. Remember that profound sepsis, enfeebled heart action, chronic alcoholism, asthma, serious valvular lesions, and severe albuminuria are the most dangerous states for anesthesia.

46.—See editorial in THE JOURNAL of November 22, p. 1327.

47.—See abstract in THE JOURNAL, xxxviii, p. 1668.

48. Bubonic Plague.—Flexner gives a very good general account of our knowledge in regard to bubonic plague, which he says has gained admission into our midst. He describes the different types and calls attention to the personal transmission of the disease. Our ideas of the subject have greatly developed in the last six or seven years; there is hardly any medical subject in which our acquisitions have been more rapid. He calls attention, in conclusion, to the danger of too great indifference to the conditions on the Pacific Coast at the present time.

49. Lymphotoxic and Myelotoxic Intoxication.—But few publications have appeared in regard to lymphotoxins and myelotoxins, as Flexner remarks in the beginning of this experimental study. He experimented extensively on guinea-pigs and notes the changes observed. The reaction of the bone marrow especially to the lymphotoxins and myelotoxins is remarked on; while the reaction of the lymph glands, intestinal lymphoid tissue, and spleen to bone marrow toxin is remarkable, the response of the marrow to lymphotoxins and splenotoxins is far less marked. The first, he says, can only be explained by the possession of numerous amboceptors common to the lymphoid cells and capable of stimulating such tissue to activity, while the smaller response of bone marrow to foreign cytotoxins may be dependent on its possession of a smaller number of cells with the corresponding receptors for fixation of the amboceptors of these sera. He also calls attention to another point. In spite of the striking hyperplasia of cells, the degenerations discovered were minute and comparatively trifling, and the glandular reactions are far behind those caused by microbial toxins, and he emphasizes the importance of the molecular or other invisible forms of injury which may occur.

52. The Dysentery Bacillus.—That the bacillus of Shiga is the cause of acute and other forms of dysentery in all climates and probably a number of summer diarrheas prevailing in the warm countries among infants is the first conclusion of Gay. He finds that guinea-pigs react characteristically and that if the bacillus is cultivated outside the body it quickly suffers a reduction of virulence for guinea-pigs, which, however, may be increased by successive passages through the body of these animals. This results in the establishment of a uniform grade or degree of virulence in the organism, irrespective of its source, which adapts it for the production of vaccines of quite uniform activity. The vaccines consist of suspensions of dysentery bacilli killed by the addition of trichresol, the activity of which undergoes an increase, for a time at least, that is coincident with disintegrative changes taking place in the micro-organisms. This vaccine suffices to protect guinea-pigs from a succeeding multiple fatal dose of living dysentery bacilli, and to produce in the horse an active immune serum. The immune serum of the horse exhibits marked protective properties in preventing fatal infection with the bacillus or intoxication with its vaccine in guinea-pigs. While the several bacilli used in the investigation belonged to one definite species, minor distinctions were present. The most marked differences noted were the weaker virulence of the "Kruse" stain as compared with the other strains of bacilli, and the slightly reduced activity both of vaccine and immune serum when directed against strains of organisms other than that from which they were

prepared. The bacillus of dysentery resists bacteriolysis by blood serum to a greater extent than some other members of the colon-typhoid group of bacilli. The use of serum therapy for bacillary dysentery and for certain forms of the summer diarrheas of infants is rendered highly promising.

54. Red Blood Corpuscle Thrombi.—Flexner's conclusions are given as follows:

1. Agglutination of red corpuscles *intra vitam* is not uncommon in infectious diseases in man and animals. 2. A special variety of thrombi is produced through this agglutination, which may be designated agglutinative thrombi. 3. When such thrombi are old, or when the agglutination is compact, they may present appearances to which the name of "hyaline thrombi" has been applied. 4. Other alterations of the blood than those arising in infectious diseases may bring about agglutinative thrombosis, the nature of this alteration being little understood. 5. Poisons which destroy corpuscles rapidly are provocative of agglutinative thrombosis. 6. The so-called "fibrin ferment thrombi" are probably nothing else than agglutinative thrombi.

55. Antihemolysis.—Noguchi's article, of which the title gives almost a synopsis, ends with the following conclusions:

1. Blood sera and milk exert more or less anti-hemolytic action against certain phyto-hemolysins and bacterial hemolysins, and their action is non-specific. 2. The manner of anti-hemolytic action of sera and milk agree with the manner of action of cholesterol and lecithin against these hemolytic agents. 3. It is highly probable that this anti-hemolytic action of sera and milk depend either wholly or in part on their cholesterol constituent. 4. Agaricin contains a hemolytic principle of considerable activity. 5. Hardened red corpuscles may still be agglutinated by ricin, venom-agglutinins, and serum agglutinins.

56. The Bacteriolytic Serum-Complements in Disease.—The following are Longcope's conclusions:

1. Normal individuals show slight fluctuations in the bacteriolytic complement-content of their blood. 2. In many prolonged chronic affections, such as nephritis, cirrhosis of the liver, and diabetes mellitus, there is a marked decrease in the bacteriolytic blood complement, which becomes more marked toward the end of the disease. 3. Terminal infection in chronic disease is probably the direct result of the diminished state of the bacteriolytic complement. 4. The blood serum of certain individuals suffering from chronic disease does not show a reduction in complement; these individuals appear to escape terminal infection. 5. Hyperleucocytosis is frequently associated with high complement-content of the blood serum for typhoid and colon bacilli. 6. The blood serum of some typhoid fever patients shows a diminution in the specific complements for the typhoid bacillus. 7. Human blood serum contains a multiplicity of bacteriolytic complements.

61.—This article has appeared elsewhere. See THE JOURNAL of November 1, title 60, p. 1131.

62. Fat Percentage.—Westcott emphasizes the following points:

1. In cases of chronic gastric or chronic high intestinal catarrh, in which underfeeding for a considerable time becomes necessary, the most satisfactory results may be obtained by the use of whey mixtures, in which the deficiency of proteids in ordinary modifications is supplemented by a high percentage of lactalbumin. 2. In many of these cases unusually low percentages of fat must be given, and for this purpose dilutions of milk without cream in conjunction with a fat-containing whey offers the most expeditious means of increasing caseinogen and of keeping the fat percentage within the bounds of digestive tolerance.

63. Milk Proteids.—The point made by Chapin is that the different results obtained by various authorities in regard to the proportion of proteids in milk, are due to the different methods of analysis and until we can learn the composition of the different proteid bodies and some uniform method of separating these, comparing the milk analyses made by different methods may lead to erroneous conclusions.

65. Bronchitis and Bronchopneumonia in Children.—The principal thing in children who continuously take cold is to increase the physical vigor, not to live or sleep in too warm apartments, with a simple diet, pure air day and night, systematic development of the muscular system, plenty of sleep, bathing and open air treatment as much as possible. Allow the child to go barefoot; the child that has not been allowed to go barefoot has lost one of the privileges of childhood. For the medicinal measures Mitchell mentions cod-liver oil for its general tonic effect, iron, and iodid of potash. Where there is enlargement of the lymph nodes, a course of syrup of iodid of iron is often beneficial, but all drugging which interferes with the appetite or digestion should be avoided. In the treatment of severe bronchitis, the cotton jacket, either with the oiled silk covering, or made by basting the cotton inside an ordinary undershirt, is a good plan. Counter-irritants he does not believe in. The question of alcoholic stimulants is to be decided by the individual case. Control of temperature is best done by a warm bath gradually reduced, with cold sponging of the head. The cold plunge bath is not well-borne by children.

Careful feeding is of great importance. For cases that become subacute or chronic, creosote preparations are of great value. Carbonate of guaiacol has been used by Mitchell; it does not readily derange the stomach. Strychnia is often useful as a heart stimulant.

71.—See editorial in THE JOURNAL of November 22, p. 1327.

78. Enlargement of the Pelvic Outlet During Labor.—The results of measurements in nine cases are reported by Neumann. Enlargement of the transverse diameter of the outlet during labor was observed in every case, the maximum being in one case 2.5 cm. It could be noted as soon as the fetal head entered the pelvic cavity. In 6 of the 9 cases a measured increase could be observed in the sacro-pubic diameter, being in one case fully 2 cm. He does not claim that this is the typical occurrence during the stage of expulsion, as he has been able to determine its absence in other cases. He thinks that the enlargement is probably produced by the force of the descending head, the pelvic articulations having been unusually relaxed during pregnancy. The question remains in what percentage does this enlargement occur, how great can it be, and what conditions favor the phenomenon? What effect does this increase or a complete absence of such exert on the mechanism, course and management of labor? He thinks that these questions can probably be satisfactorily answered if such measurements are made more extensively with more general use as a mode of examination of the x-rays.

79. Cardiac Dilatation in Puberty.—The cardiac dilatation that occurs from over-exertion in young children and especially at the age of puberty when they begin to use more muscle strain, particularly in the case of boys, is noted by Friedlander. The symptoms are dyspnea, weakness after even moderate exercise and often severe palpitation at such times, pallor, some times even cyanosis, capricious appetite and disturbance of sleep. These become more manifest the longer they are allowed to go uncorrected and the longer the exciting cause is allowed to exist. Physical examination shows a diffuse apex beat to the left of the mammary line, an increased area of precordial dulness, prolonged first sound at the apex or possibly a distinct systolic bruit. The question then is whether we have to deal with some grave heart disease or simple myocardial weakness, especially if there is an antecedent rheumatism or chorea, and the signs and symptoms of valvular lesion be present. Such cases are, however, exceptions. In uncomplicated cases the prognosis generally is good, the recuperative power of the heart muscle is sufficient to bring things around to the normal if the cause is removed. Exercise should be restricted and in severe cases it is best to put the patient to bed. The diet should be light and nutritious, but should have a minimal quantity of fluid. Liquid food given in small quantity is best. In the beginning if there is much irregularity of the heart's action, digitalis is often of value, and strychnia is frequently of service at all stages. The principal thing, however, is to rest the heart, not to stimulate it.

80. Inebriety.—Crothers summarizes his views that the periodicity of the drink paroxysm is evidence of central brain disease, and that heredity, nutrition, mental exhaustion, and environment are all very common causes or predisposing factors of this condition. Allied diseases, of which epilepsy is very common, are frequently interchangeable or associated. The drink periodicity follows a uniform line of events. These are the most uncertain and dangerous of all drink neurotics and are the least understood. The prognosis is uncertain and full of dangerous possibilities. Very important medicolegal problems are associated with them, and each case requires especial study.

83.—See abstract in THE JOURNAL of October 25, p. 1064.

88. Optimism and Pessimism in Medical Practice.—The principal points made by Inglis in his article are the needlessness of the too common pessimistic views in regard to certain forms of nervous diseases, such as hysteria and neurasthenia, each of which is capable of the most sudden and rapid improvement. It is important in these cases not to help the morbid condition by pessimistic suspicions or attitude on the part of the physician and the special importance of this in

medicolegal cases is noted. Even serious organic nervous troubles like locomotor ataxia often have not the bad prognosis that is too commonly given them. Many cases of locomotor ataxia he believes can be improved, not only in symptoms, but the sclerotic areas may diminish. Even in infantile paralysis the great majority of cases could be spared their deformity if the physicians were impressed with the fact that countless new cells in the spinal cord are going to develop and take up their activities.

90. Ophthalmia Neonatorum.—Campbell reports cases of entropion, perforating corneal ulcer and secondary glaucoma with buphthalmos.

91. Typhoid Fever.—Duffield believes in intestinal antiseptics and finds that guaiacol meets the needs better than any other remedy. He usually gives 5 minims every three or four hours in capsules and has often noticed a special antipyretic effect, though given for its antiseptic properties. Its local application has taken the place of baths with him for many years. He employs it over the ileocecal valve, rubbing in four or five minims gently and covering with cotton wadding. The skin seems to absorb the remedy quickly. As regards diet, he objects somewhat to the exclusive milk diet because milk is not a fluid within the body, but he allows plenty of sterile water, beef broth, beef juice, strained animal broths and certain artificial foods. As the fever abates, the broths may be thickened and a soft diet be substituted gradually.

93. Normal Saline Solution.—Campbell uses normal saline solution in many conditions, aside from emergency cases, for loss of blood. He finds it valuable in the hemorrhages of typhoid. It is an extremely valuable adjunct. Heart disease, hemophilia, atheroma, apoplexy, chronic diseases of the lungs, kidneys or liver are all contraindications.

95. Drainage.—Clark thinks drainage is still too much followed. It simply means untidy surgery and hinders the free exit of pus and infectious matter. It introduces a foreign body, leads to infection, is often difficult to remove, weakens the abdominal wall and leads to hernia, retards the healing of the wound, may be the cause of great pain and serious accidents in its removal from adhesions and may also cause fecal fistula.

96.—See THE JOURNAL, xxxviii, §144, p. 793.

99. Retention of Urine.—The retention of urine from acute inflammatory injuries and organic stricture and senile enlargement of the prostate are all noticed in detail with their treatment by Brinton.

100. Chronic Nephritis.—Anders remarks that carefully selected hygienic treatment may often retard or arrest the morbid processes in this condition, and he advises a mixed diet with some digestible vegetable and starchy foods in most cases. An absolute milk diet is recognized to cause, by the ingestion of massive quantities of fluid, increased blood pressure and overwork of the heart, an objection which is often overlooked. He does not find that the proteid foods necessarily cause uremia, though an excessively animal diet may have some such effect. As regards uremic convulsions he finds dry cups applied over the loins exceedingly effective, and better than diuretics. He speaks highly of venesection in this condition followed by normal saline solution administered intravenously. The question of the use of morphin is discussed and experience shows that it is less harmful than might be expected. In acute nephritis and in chronic nephritis it should only be applied after other remedies, including jaborandi and venesection, have failed or are contraindicated by too great feebleness of circulation. Chloroform has some advantages in uremic convulsions, it being a rapid remedy. Cerebral hemorrhage should be treated as in other conditions. When a hypnotic is needed, sulphonal, trional, and chloralose are the best drugs. For the headaches associated with renal disease, palliation is the only possibility. Restriction or regulation of diet may do some good. Phenacetin (5 or 10 grains) combined with caffeine (2 to 3 grains) in capsules, every third hour has had good effects in his hands.

101. Strychnin.—Curtin protests against the too common overdosing with strychnin.

102. Eclampsia.—The treatment of puerperal eclampsia is summed up as dietetic, hygienic and medicinal, an exclusive milk diet without any beef preparations or other foods, frequent bathing, keeping the skin active, diuretics, when necessary, and laxatives or cathartics, with high enemata if we can not give enough water by the mouth, and calomel in small doses frequently repeated. To control the convulsions the following are the chief agents: chloroform, veratrum viride, morphin and chloral. Chloroform must be given almost constantly during the convulsive stage and the stage of coma. Norwood's tincture given hypodermically is useful only in plethoric women with a full, bounding and rapid pulse. Morphin should be given cautiously because of its possible effect on the excretory function of the kidney, and if possible not given at all. Chloral can be given with or without the bromids. Forced delivery with as little damage to the mother as possible is the treatment to be relied on.

103.—See abstract in THE JOURNAL, xxxviii, p. 1390.

105.—See editorial in THE JOURNAL of November 22, p. 1327.

106. Thiosinamin.—The action of thiosinamin is, Somers says, elective for poorly organized tissue, especially cicatricial and fibrous, and he reports a dozen cases of aural disease thus treated in doses of $\frac{1}{2}$ to 1 grain, three times daily in capsules. In a few recent cases he gave three grains daily in divided doses for two weeks, then increasing to 6 grains daily, but found that it produced nausea. At first he used it to the exclusion of all other remedies, but he found later that it was better adapted for an adjunct than an exclusive treatment. It has certain contraindications and it should be avoided in case of existing old fibrous tissue which acts as a support to important structures, and also in active inflammatory processes if it aggravates them. In his cases the results seemed to be generally satisfactory.

108. Formin.—Snider recommends the use of formin and gaduol, reporting a case of kidney complication of miscarriage where they were employed. He thinks formin has a special value in the puerperal states of the kidneys.

111.—See editorial in THE JOURNAL of November 22, p. 1327.

118.—This article has appeared elsewhere. See THE JOURNAL of November 15, title 26, p. 1278.

124. Lateral Sinus.—Powers reports a case in which an abnormality existed of the lateral sinus which extended directly under McEwen's triangle and the fossa mastoidea so that there was no possible means of entering the antrum without first going through the sinus transversus.

125. Uterine Carcinoma.—The inoperable and hopeless cases of uterine carcinoma are, as Stapler points out, often greatly relieved by treatment, caustic applications, etc. For operable cases the only thing to do is to resort to surgery as soon as possible. He gives the details of Wertheim's operation, which is the ideal of a radical treatment. (See Wertheim's latest report, §48, p. 1491.)

127. Fractures.—From the cases here reported, Stratton deduces the following conclusions:

1. The management of fractures which are in locations most frequently the site of delayed or non-union, namely, the shafts of long bones, and especially those of the lower extremities, should receive treatment, adapted to prevent as far as possible failure of prompt union.
2. This should be most carefully followed in individuals of low general vitality from any cause, and especially when associated with the abuse of alcohol.
3. This preventive treatment is also demanded in cases in which the nutritive processes at the site of fracture are deficient by reason of the extreme violence of the traumatism, or former bone injury, or existing bone disease, with or without loss of bodily tone.
4. That in cases of simple fractures, at least, local and general massage, electrification, stimulating frictions, out-of-door life, change of climate, and detailed attention to the state of bodily health, are well-known means of securing a higher degree, not only of general vigor, but also local nutrition of the injured limb, which need to be more generally considered in relation to the prevention of these complications.

131. Hyoscin Hydrobromate in Alcoholism.—Bering reports a case treated according to the method recommended by Lott, with frequently repeated doses of $\frac{1}{100}$ grain of hyoscin hydrobromate, followed later with pilocarpin, the man taking altogether 43 doses of $\frac{1}{100}$ of a grain inside of three days. He was apparently entirely cured, not only of his chronic alcoholism, but of the effects of the drugging. [The remedy

seems risky thus employed considering the effect of hyoscin in some cases.—Ed.]

1. **Pneumonia.**—Duckworth's treatment of pneumonia consists of fever diet, mainly milk and beef tea, the reduction of excessive temperatures, both by sponging with ice water and local applications of ice, by Leiter's tubes or a similar arrangement. The plunge bath, he says, is not well borne and is exhausting, nor does he advise coal tar antipyretics. He advises 5 grs. of quinin every two or three hours until the temperature falls, and recommends a simple fever mixture of potassium citrate and ammonium acetate. Quinin is perhaps the most valuable drug, in 2 or 3 grain doses every three hours. After a day or two one may add a little compound tincture of bark to the fever mixture, one-half to one dram to each dose. The lungs should be carefully examined without exhausting the patient. After four or five days the fever usually breaks. If it does not, look out for complications; there may be an empyema which usually begins with pneumonia. There is a possible abortive type, the patient is ill and there may be herpes or some symptoms of lung disease, but the crisis may come on the second or fourth day and all the symptoms pass off. The occurrence of herpes is on the whole a rather favorable symptom, though he does not say why. Pneumonia in the drunkard is most certainly a deadly disease and double pneumonia is absolutely fatal. Influenzal pneumonia is severe, especially in elderly people. Opium may be beneficial in some cases, but it should be used with care and only where there is no reason to suspect kidney involvement. Heart failure is a severe complication to be looked for after middle life. Oxygen is advised and hypodermatics of stychnia. Duckworth speaks highly of the use of musk; he generally combines it with Hoffman's anodyne, and gives it at short intervals. A mercurial purge may be given in the beginning of the case, and the bowels will probably not require attention later. In winter time successions of hot poultices may be applied to the affected side and in hot weather be replaced by cotton wool sprinkled with spirits of camphor. The study of the temperature chart, and especially of the conditions of the heart are advised.

2. **Diazo-Reaction in Tuberculosis.**—De Boissiere reports observations and finds that the diazo-reaction occurs in a comparatively small number of cases (18 out of 130 cases examined). When present it is usually in cases of definite pyrexia and is associated with an advanced stage of the disease. In many advanced cases, however, it is absent. His findings disagree with those of Bolli in regard to its frequency, but he thinks that it has a certain prognostic value. Its presence is to be regarded as of grave significance if persistent and its disappearance considered a happy omen.

3. **Hyperpyrexia.**—The two cases reported are one of probable influenza in which the temperature ran up to 111.5 with recovery, slow but good, and the second was a case of liver abscess where the temperature rose to 110. In both cases the thermometers were compared and tested.

4. **Concurrent Scarlet Fever and Measles.**—Dent reports a case where these two diseases occurred in two persons of the same family and he suggests the possibility of the so-called "fourth disease" being an analogous mixture of German measles and mild scarlet fever.

8. **Pneumonia.**—This first Croonian lecture deals with the bacteriology.

9. **Public Health.**—Several points specially noted by Dill in his presidential address, are the danger to the public from syphilis, which he thinks is neglected in public medicine, the victims of it being perfectly free to extend the disease without any legal restrictions whatever; alcohol; the increase of insanity and its inheritance. He thinks the time is ripe for a considerable enlargement of the list of notifiable diseases, including syphilis, drunkenness and insanity. It would probably be advisable to compel those intending to marry to provide themselves with a certificate of health made on a special form like those of life insurance companies and with particular reference to hereditary disorders.

10. **Cardiac Pain.**—In this third lecture, Morison draws from the total of his studies the conclusion that the exclusive arterial views of the malady must be abandoned. The rôle of the blood vessel as a hemaduct has been exaggerated; it is more than a simple duct, it is a muscular organ, innervated,

irrigated, mobile and capable of being disabled like the heart in its muscle, its blood supply and its nerves. Angina pectoris, contrary to Huchard's views, is probably not a single disease, excepting in its symptom of cardiac pain, but is essentially three-fold, muscular, neurotic and hemic. As regards etiology he holds that it is not the rise of blood pressure as such which causes angina, but blood pressure in many cases, whether propulsive or obstructive, exercising its influence on local anatomic lesions or strained physiologic structures in the heart or in its immediate neighborhood.

11. **Liver Carcinoma.**—Acland and Dudgeon report a case and discuss the literature. They find that practically little is known with certainty as to the origin of primary carcinoma of the liver.

12. **Gall Bladder Exposure.**—Five cases are briefly summarized and Pollard is much impressed by the advantages of the Mayo Robson incision, namely, a longitudinal incision in or about the linea semilunaris and an oblique incision passing downwards from the middle of the rectus at the costal margin. This combined oblique and longitudinal incision can be employed without dividing the fibers of the rectus muscle. It can be split over the lower costal cartilage and the inner half be retracted inward without division, sufficiently to allow of the transversalis muscle and the peritoneum beneath being divided right up to the interval between the costal margin and the ensiform cartilage and the liver pushed forward by the sandbag; prolapses through the wound and its lower portion can be everted through the costal margin so as to display the biliary passages most completely and the ducts pushed and pulled forward, occupy such a superficial position that he, like Mayo Robson, has found it quite easy to stitch up the wounds of either the common duct or cystic duct with a small curved intestinal needle, held between the thumb and forefinger. The help afforded by the sandbag behind the hepatic region is very real, as is shown by the altered position of the parts when the sandbag is removed.

14. **Alcohol.**—Wilks considers alcohol a beverage and a medicine. He thinks some medical men are too indiscriminate in its use and he has had to diagnose drunkenness as the cause of the symptoms seen in cases where he was called in consultation. As a remedy in nervous disease, alcohol is invaluable and it has a place as an anodyne, but the greatest care must be used in its administration, especially in cases of low spirits and general mental despondency. The term "sedative" denotes its action in fever, since a stimulant ought to aggravate the condition. The question of diet is entirely outside the domain of the medical man. People will take liquor because they like it and the question is one of appetite.

15.—See editorial.

16. **Alcohol.**—Broadbent finds alcohol useful as a stimulant, that is as an indirect one. It should never be given in the early stages of febrile disease even when the patient is in the habit of taking it. Later the indication for its employment is not muscular prostration and weakness of which the patient may complain. We should be guided by the pulse, its frequency and low tension with dirotism and anacrotism, rather than by its apparent strength; the dry state of the tongue, and sordes about the lips, teeth and palate are indications for alcohol. To promote sleep alcohol is valuable. Its odor on the breath should be noted, and, if marked, should be an indication for the discontinuance.

17.—See editorial.

18.—See editorial.

19. **Alcohol in Surgery.**—Gould first notices the importance of alcohol in furnishing subjects for surgery and then as a complication in surgical cases and its uselessness and danger in septic conditions. He does not think it an aid in the repair of wounds and the convalescence from severe injuries, nor does he think alcohol of primary value in the treatment of shock or collapse. It is of use only in helping to tide over an emergency. It may be of some use in cases of advanced cancer as a sedative or to help appetite, but anything like the free use of alcohol is to be deprecated.

20. **Hypnotism in Alcoholism.**—Bramwell reports cases thus treated and insists on the importance of beginning treat-

ment at the commencement of a period of quiescence and securing the patient's co-operation. Patience on the part of the operator and persistence in suggestion of the distaste of alcohol are emphasized.

21. Sociologic View of Alcoholism.—Ridge gives a tabulated statement of the expenditure for drink during the nineteenth century, showing that it has more than quadrupled; that the cost per head has risen from £2 4s. 2½d. (about \$10.70) in 1801 to £3 18s. 8d. (about \$19.07) in 1900. These figures, he holds, are less than the amount actually paid, as the spirits reckoned above are broken down by the dealer and sold diluted, thus realizing more money. While there has been an aggregate improvement in the drink habit of the people in certain ways it shows a serious aspect of the case, for this increased amount is used by a smaller proportion, therefore we have more excessive drinkers. The author notes the changed standpoint of medical men in regard to alcohol within the last few years.

22. Mortality from Alcohol.—Vacher's report is entirely statistical, giving the data for the last twenty years, 1881 to 1900. The figures are in some respects rather curious. They show the large proportion of deaths from alcohol occur at an age when men should be at their best and the registrar-general's figures make a rather remarkable contrast between the extremes of mortality in the different parts of Great Britain. From this showing Cornwall seems to be the most temperate section, while Lancashire heads the list of alcoholic mortality.

35. Differentiation of Eosinophiles.—Audibert reviews the different points in the differentiation of eosinophiles and the possibilities of error in technic.

36. Pathogenesis of Sublingual Cysts.—Cunco and Veau claim that they were the first to suggest and establish that the sublingual dermoid and mucoid cysts or ranula, called "little frog" also in French and "frog tumor" in German, are the first links in a series of neoplasms that originate in the embryonal clefts. The series, starting with the ranula, includes the moderately malignant mixed parabuccal tumors and terminates in the branchial epitheliomata of the neck which are essentially malignant. The ranula develops from epithelial debris left in the depths of the cleft as the external groove closes. The relations between it and surrounding parts, its evolution and its histology all sustain this view.

37. Indications for Bottini Operation.—Desnos thinks that the indications for this operation are along the same lines as for internal urethrotomy. Both aim to remove the obstacles that have developed at the orifice or in the lumen of the passage. On the other hand, perineal prostatectomy bears more analogy to urethrectomy, as its aim is to free the periphery of the passage by removing the masses of pathologic tissue which surround and compress it. The indications for the Bottini operation are therefore slight hypertrophy of the prostate, with the middle lobe protruding into the bladder, or with bars interfering with miction and entailing more or less retention. It is less successful in hypertrophy of the lateral lobes, and is not at all applicable for hypertrophy encircling the outlet of the bladder and the urethra. In these cases of peripheral rather than orificial hypertrophy the result of the Bottini operation is insignificant and far from durable, while total prostatectomy is specially indicated. Infection of the urinary passages is not a contra-indication to the Bottini unless long established, in which case an intervention allowing good drainage, such as perineal prostatectomy, is preferable.

38. Improved Technic for Spinal Cocainization.—Nearly all the drawbacks of spinal cocainization can be obviated by using a solution of cocain 2 gm., sodium chlorid .15 gm. in 50 gm. water, as follows: Each quarter of a cubic centimeter contains 1 cg. of cocain. The solution is kept in sealed bulbs containing 1 c.c. The contents of the bulb are aspirated into a syringe with a capacity of 3 c.c. The fluid is then all expelled except the half centimeter that is to be injected. The lumbar puncture is then made and about ten drops of the cerebrospinal fluid are allowed to escape. The syringe is then adjusted to the needle and the cerebrospinal fluid is aspirated into the syringe, where it mixes with the solution of cocain already in the syringe. The whole is then slowly reinjected.

No noticeable headache, nausea or hyperthermia were observed with this technic in an experience with 70 subjects. Almost all asked for food at once. A few vomited a little, fifteen minutes after the operation, and 2 had headache that commenced twelve and twenty-four hours afterward, but soon subsided.

39. Leucocytosis in Infectious Diseases.—Bezangon and Labbé proclaim that the leucocyte formula in disease is the composite image of the local reactions to the microbes at the primary morbid focus, plus the image of the secondary reactions which occur in the blood-forming organs at a distance. Polynuclear leucocytosis is the reaction manifested by the organism whenever an infection by its acute onset necessitates an early and rapid effort to combat it. This reaction is sufficient in superficial infections caused by germs of moderate resisting power, but it proves inadequate to free the organism of germs which are difficult to destroy. Mononuclear leucocytosis, on the other hand, is a reaction that takes place more slowly, but is more durable in its action and is the only one capable of triumphing over a profound and tenacious infection. Hence it follows that infections causing a polynuclear leucocytosis, which represents merely a slight superficial reactional effort on the part of the organism, are followed by only transient immunity, while the mononuclear infections, which necessitate a prolonged effort on the part of the organism, generally confer a solid and durable immunity. Hyperleucocytosis with polynucleosis is chiefly encountered in the saprophytic affections, in localized inflammations, in suppurations, erysipelas, pneumonia, etc., in diphtheria, gonorrhea and scarlet fever, and is accompanied by hyperfibrinosis. Hyperleucocytosis with mononucleosis is the appanage of specific diseases, such as mumps, whooping cough, syphilis and tuberculosis at certain stages. It is also encountered, with abnormal leucocytes, in variola, varicella, etc. Typhoid conditions, typhoid fever, typhus and malaria, induce leucopenia with relative mononucleosis. The curve of the leucocytosis generally parallels the course of the disease. Return to normal is preceded by certain special modifications in the leucocyte formula, such as mononucleosis, appearance of transitional forms and reappearance of the eosinophiles which disappear during the height of the malady. The various infectious diseases do not have any specific leucocyte formula. The blood formula is merely a symptom, but it is constant and varies little during the course of the disease. Any disturbance in this average pathologic leucocyte formula denotes a serious, abnormal, complicated course, and is thus valuable for the prognosis. Leucopenia is a grave sign. It indicates an insufficiency in the reacting power of the blood-forming organs. Excessive hyperleucocytosis and polynucleosis indicate a violent and stubborn infection necessitating violent reactional effort on the part of the organism.

41. Operation for Large Genital Prolapses.—Bouilly's method consists in a high amputation of the hypertrophied and sagging cervix, excision of the superfluous vaginal wall and anterior colporrhaphy and colpoperineorrhaphy. It is a complete and permanent cure of all such cases. The technic is readily comprehended from the eight large cuts.

42. Ventroscopy Through the Vagina.—De Ott's communication was reviewed in THE JOURNAL of August 23, and three of the illustrations reproduced.

43. Primary Tuberculosis of the Cervix.—There are only 3 cases of primary tuberculosis of the cervix on record, and 2 were autopsy discoveries. Brouha has observed a fourth case. The symptoms were masked by those of a pronounced hemorrhagic interstitial endometritis. The uterus and adnexa were removed by abdominal section as it was impossible to determine the extent of the tubercular lesion in the cervix. The patient has been in fine health since. The cervix was found the seat of an actual tuberculous cavity, funnel shaped, and confined exclusively to the neck. The patient was clinically free from any other tuberculous manifestation then and since. He regards it as a case of ascending tubercular infection, primarily localized in the cervix. The patient's husband had died from pulmonary tuberculosis six years before, and the depth and chronic character of the lesion suggested that the infection dated from several years previously.

44 **Technic of Maydl's Operation for Exstrophy of the Bladder.**—Ten large cuts give a good picture of the various steps of the intervention.

45 **Treatment of a Hernial Anus.**—Pauchet plugs the anus with a tampon and then incises round it to mobilize a collar of skin surrounding the anus. This circle of skin is drawn up over the anus and pinched firmly with forceps like a cover over it. The entire loop of the intestine is then drawn out and the two parts are united by lateral anastomosis after the portion containing the anus has been cut off and the stumps thermocauterized and closed with a purse-string suture. The patient ingests nothing by the mouth for forty-eight hours, after which he commences on fluid foods, but no milk is given for a week. He describes 4 cases and illustrates the technic.

46 **Hysterectomy for Uterine Cancer.**—Pozzi's address was reviewed in *THE JOURNAL* of November 1, p. 1146.

47 **Surgical Treatment of Uterine Cancer.**—Jonnesco's article is illustrated with 52 large cuts. He advocates ablation of the uterus and adnexa in case of cancer, removing also the cellulofatty tissue of the pelvis, iliac fossae and lower lumbar regions with all the lymphatic vessels and ganglia contained in it. The field of operation is drained through the vagina, the long wicks replaced by a short one in twenty-four hours. He proclaims that this thorough evacuation is a rational, possible, benign, easy and effective operation for removal of malignant disease, when the lesion is circumscribed, and it is possible to remove everything and leave none of the cellular tissue and lymph ganglia. The free margin of the pelvic colon is sutured to the iliac and vesical peritoneum to shut off the abdominal cavity. He does not undertake this operation unless the patients are still in comparatively good health. He has operated by this method eighteen times during the last two years. In 10 cases the cancer was circumscribed and the patients recovered rapidly. In 8 the parametrium was already involved, and 3 of the patients have since died. There has been no recurrence in any case.

48 **IBID.**—Wertheim states that he has examined under the microscope 7000 sections in series of the parametrium and ganglia taken from 80 cases of cancer of the uterus on which he had operated. He found that the malignant disease had already invaded the parametrium in 45, and on both sides in 26. The parts involved were not in direct connection with the uterus. In 55 the cancerous degeneration had reached the outer part of the parametrium. In 11 the foci were entirely independent of the primary neoplasm. The ganglia accompanying the large vessels were found cancerous in 23 cases, on both sides in 4 and in 27 on one side. The involved ganglia were generally isolated, and very seldom was a whole group affected. In 22 cases in which the parametrium had been invaded by the cancer the ganglia were apparently intact, while in 4 in which the latter were affected the parametrium was exempt. In 32 instances both were apparently sound. In short, in 48 out of the 80 cases ablation of the uterus alone would not have removed all the cancerous tissue. He removes the parametrium as close to the walls of the pelvis as possible, drawing the ureters aside. He also resects all the ganglia that show the least trace of enlargement. In 120 operations for uterine cancer his mortality was 12 in the first 30, 5 in the second, 3 in the third and 4 in the fourth. This is a total mortality of 20 per cent, or including only the last three groups, of 13 per cent. He is careful to refrain from isolating the ureters from their nourishing vessels, and he also prepares for the hysterectomy by thorough curettement and cauterization of the cancer, packing the cavity with cotton impregnated with bichlorid. He avoids a tendency to pressure of the bladder later, by fastening its wall, after divesting it from its peritoneum, to the anterior wall of the vagina. This reduces the size of the bladder, and some of his patients have been able to urinate spontaneously from the first day. By operating along these lines he has been encouraged to extend the scope of surgical intervention. At first he operated on only 29 per cent of all that applied, but in his last two series he has operated on 50 and 52.9 per cent, notwithstanding numerous and serious complications in a number. There has been no recurrence

in 77 per cent of the 13 operated on more than two and one-half years ago.

49 and 50 **IBID.**—Cullen remarks that with Wertheim's method he does not believe that there is much further progress to be made in the line of operative treatment of cancer of the uterus. He does not approve, however, of the practice of preliminary curettement and cauterization of the lesion as it depresses the vitality of the patient. He prefers Sampson's method of severing the uterus above the infiltration and inserting it in the bladder. He also considers it important to prevent hemorrhage from the vaginal walls by encircling the vagina with deep interrupted catgut sutures before opening the abdomen. This little measure does not require more than five or six minutes, but it prevents the least loss of blood from this threatening source. Freund referred to two of his patients who were free from recurrence now twenty-four years after abdominal removal of a cancerous uterus.

53 **Hysterectomy for Puerperal Infection.**—Fieub had 690 patients with puerperal infection who have recovered and 34 who died. In 6 of the latter number there were no clinical signs of any infection outside of the uterus, but the autopsy disclosed acute septic nephritis, purulent thrombosis or some other serious lesion in all but 2. Consequently out of the total number there were only 2 that might have been saved by a timely hysterectomy. He has collected 36 cases of ablation of the uterus as a means of treating puerperal infection with no extra uterine localization or uterine complication such as retention of placenta, fibromata, etc. Fifteen out of the 36 recovered and they might have recovered without the hysterectomy as he corroborates by certain cases in his experience which came to a spontaneously favorable termination, although apparently doomed. Bacterial examination of the blood is no criterion. Freund has known cases of prohemia following criminal abortion which recovered spontaneously, and consequently does not endorse Freund's opinion on this subject. Nor does he agree with Cantledge in his assertion that "non-operative treatment of puerperal infection, if it is going to be successful will arrest it in three days." Puerperal infection does not go by the clock, he remarks. He also refutes Vineberg's assertion that a pulse of 130 indicates a fatal prognosis, as numbers of his patients who afterwards spontaneously recovered had a higher pulse than this. In short, there are no absolute indications at present for hysterectomy in puerperal infection. In a few exceptional cases it may succeed after obstetrical treatment has completely failed.

54 **IBID.**—Leopold thinks that antistieptococcus serum or some similar serum may yet prove effective in these cases. He urges careful search for all the foci of suppuration, and is inclined to believe that the extirpation of veins affected with suppuration will yet lead to brilliant successes in some of the severest cases of puerperal infection.

56 **Traumatic Edema.**—Vulliet has observed a number of cases of these lesions of the back of the hand and foot, which are so painful that they prevent the use of the hand and do not subside for eight to twelve weeks in some cases. There is no inflammation, but a fibrous, diffuse exudate between the loose skin and the hard background of the back of the hand or foot, consecutive to trauma. Warm baths are beneficial, but massage has proved injurious. Compressing bandages did not hasten the resolution of the tumor in his experience.

57 **Rectal Prolapse in Infantilism.**—The rectum was given a new support by the operation in the case described. The walls of the Douglas pouch were sutured together and the sigmoid flexure was pulled to the right. The mesocolon between the two ends of the loop was sutured together, while the intestine was sutured to the periosteum and peritoneum of the sacrum and right pelvic wall on one side, and to the broad ligament and rear peritoneum of the uterus and left pelvic wall on the other side of the loop formed by the intestine. The sagging vaginal wall was taken up by Freund's method of perineal plastics, and later, a wire ring according to Thiersch's method was introduced which healed in place without reaction. The prolapse was thus completely conquered and the conditions have remained normal during the year since.

58. Spinal Cocainization Without After-Effects.—Kozlowski reports that in an experience of 32 cases he has avoided all after-effects of spinal cocainization by his technic. A single needle prick, he says, enabled him to perform all operations on the legs and pelvis absolutely free from pain, and with no inconveniences afterward. He uses tropacocain, and puts 5 cg. of the powder in a warm, sterile, graduated dish. He then makes the lumbar puncture and allows the cerebrospinal fluid as it issues to drop on the tropacocain. The latter dissolves readily in the fluid, aided perhaps by slightly shaking the dish. When 5 gm. of the cerebrospinal fluid are thus caught in the dish, the result is a 1 per cent. solution of tropacocain which he then aspirates into the syringe and injects at once. He does not sterilize the tropacocain (Merck's).

60. Radical Treatment of Congenital Inguinal Hernia in Children.—Kremm turns the hernial sac wrong side out after reducing the hernia, and sutures the two serous surfaces together, with the cremaster and transverse fascia. This forms a solid cylinder, and he then proceeds as in the ordinary Bassini operation.

62. Apparatus for Hypodermoclysis.—The little apparatus which Oliva has found extremely useful in private practice consists of a receptacle for the fluid to be injected, with a long tube terminating in the needle. This tube is enclosed in a larger tube which terminates just below the needle in a right angled branch with faucet. The needle and tube are sterilized before using, and the water in which they are boiled is poured into a fountain syringe, the tube from which runs into the outer tube near the top. It flows through the outer tube and the terminal branch into a receptacle on the floor, or the faucet can be turned to retain the hot water in the outer tube. This warms the fluid to be injected in the inner tube, and keeps it at an even temperature. The needle is enclosed in an adjustable outer shell with a blunt tip which prevents the needle from entering too far or changing its position when once introduced into the vein.

64. Development of the Placenta.—Hitschmann's research seems to establish that when the ovum settles on the mucosa of the uterus it penetrates into it and becomes surrounded by a peculiar layer of trophoblasts or ectoblasts which possess the power of invading the veins without interfering with the circulation in them. Coagulation of the blood does not occur, and the blood circulates freely through the spaces between the villi. The process seems to be identical with that of the invasion of malignant chorion-epithelioma. In the latter case this non-interference with the blood current explains the sweeping away of fragments. As the trophoblasts surrounding the ovum penetrate into the vessels, the villi keep pace with them. The career of the trophoblasts is brief, and when it is ended the circulation through the villi is established and continues, but the penetration of the villi into the decidua and the opening up of the vessels cease as soon as the trophoblasts die. The placenta and the ovum grow, but their relation to the maternal tissues remains unaltered after the trophoblast stage is past. The etiology of placenta previa is readily explained by this assumption, as he shows by numerous cuts.

66. Pregnancy with Rectal Cancer.—Rossa's is the only case of this kind that has been published, he states, in which the pregnancy terminated spontaneously at term with the delivery of a healthy child. The patient had noticed for two months severe pains localized in the sacrum and buttocks, and difficulty in defecation, but had assumed that they were connected with the pregnancy, and kept the pains under control with morphin. The latter finally lost its efficacy, and she then for the first time allowed an investigation. A carcinomatous stricture was discovered. Fecal masses had collected above it in large amounts; after their evacuation labor proceeded normally with delivery in five hours. She refused an operation for two months longer, by which time the neoplasm had increased considerably in size, but was still circumscribed and was extirpated. All physicians should suspect cancer in case of pains localized in the sacrum and buttocks with difficulty in defecation, and insist on an examination in pregnant women the same as in the non-pregnant. Durable cures can be anticipated when

the pregnancy is interrupted at once in such cases and the neoplasm extirpated in its early stages.

68. Physiologic Albuminuria.—Leube's article was one of the addresses at the Naturforscher Congress. He proclaims that physiologic albuminuria is merely due to the greater or less porosity of the renal filter in healthy persons. In very rare cases this filter is so porous that it allows the passage of albumin in normal conditions and in the absence of predisposing factors. In other persons this filter is so dense that the albumin never filters through under any circumstances. The third category comprises persons with a moderately porous filter which does not allow the passage of albumin at ordinary times, but under the stress of unusual exertion, emotions, long standing, etc., the congenital porosity of the vascular membrane allows the passage of albumin into the urine. He thinks that this group is much larger than usually recognized. The albuminuria in these conditions is not pathologic and there can be no question of treating it. The subjects are healthy and can lead normal lives. In differentiating it we must exclude cases of subsiding or incipient nephritis, or an insidious interstitial inflammation of the kidney, and also the albuminuria of adolescents. The cause of the latter is principally that the regeneration of the blood and the heart action are unable to keep pace with the rapid growth of the body, and any extra exertion taxing the heart entails intermittent albuminuria. He thinks the term "cyclic albuminuria" should be discarded. This albuminuria of adolescents is not a physiologic albuminuria but an affection that requires treatment. Avoidance of over-exertion, repose, sleep and general hygiene, abundance of wholesome food and avoidance of stimulants and of all substances that might irritate the kidneys, are usually sufficient. There is always a suspicion that the kidneys of such persons may be more predisposed to nephritis than others.

69. Osmotic Dieting.—Strauss has been studying whether it may not be possible to influence the osmotic processes in the body by the diet. The results suggest that the polyuria in certain cases of nephritis may be a necessary compensating process. The subjects require a larger amount of water as the vehicle for the normal amount of solid elements. The quantity of water ingested should not be restricted, but the heart should be spared so far as possible all other demands. Retention of salt leads to retention of fluid in some cases of nephritis. The nephritic kidney responds less rapidly and with less intensity in osmotic variations to changes in the diet than a sound kidney. Strauss' research opens up new problems without solving any.

71. Review of 720 Gallstone Laparotomies.—The surgical aspect of Kehr's article was reviewed in THE JOURNAL of November 29. In regard to internal treatment he adopts the general opinion that the aim should not be to expel the stones but merely to keep them quiet in the gall bladder and reduce inflammation. This can best be accomplished by a few weeks of hot applications, preferably the thermophore, rest in bed and a course of Carlsbad waters. He does not operate in cases with mild attacks and no sensitiveness of the gall bladder region in the intervals. Acute occlusion of the bile duct should usually be treated medically until the strength and appetite decline as the cholangitic phenomena predominate and the icterus persists. Icterus with evacuation of stones at each attack, belongs to the internists, as also the rare cases of sterile hydrops, so long as it does not cause trouble. When the colics have led to morphin addiction operation should be done, as also in chronic occlusion of the bile duct, and without delay. He has operated 1131 times during the last twelve years, and 536 of his 655 patients were women. Men, especially fat men, bear the intervention poorly. Women who have borne children are the best subjects. The gallstone affection was complicated by stomach trouble in 12 per cent. He urges internists to be present occasionally at gallstone operations.

72. Vibration Massage to Hasten Expulsion of Kidney Stones.—Klemperer states that in 6 out of 10 cases of renal colic expulsion of the stone followed the application of vibration massage to the affected side. The procedure usually induced a fresh attack of colic, which terminated in the passage of the stone.

77. Arsenical Neuritis.—Janowski concludes from his experience with 3 cases and 129 in the literature that arsenical neuritis has a tendency to spontaneous retrogression. Patience on the part of physician and patient is needed. Early active treatment can do only harm. Electricity is strictly contraindicated in the first and second stages, but after the subsidence of all pains and recovery from muscular atrophy, it can be cautiously applied with massage, baths and passive gymnastics. The greatest relief at first was obtained from large hot compresses applied to the entire extremity, with potassium iodid. Morphin should be used with great caution.

79. Hemorrhage from Erosions in the Stomach.—In both of the cases described by Mintz vomiting was the predominant symptom. It simulated nervous vomiting and was treated six months on this assumption, but without results, until particles of mucosa and blood were discovered in the vomited matters. The trouble can be differentiated sometimes only by the constant finding of scraps, which the microscope shows to be particles of gastric glands. Isolated fragments may occur sporadically in the healthy stomach contents, but their constant recurrence differentiates the erosion. His patients were young women of leisure, whom he treated with lavage of the stomach with a 1 or 2 per 1000 solution of silver nitrate, after copious rinsing, and large doses of bismuth. If the silver lavage is ineffectual the patient should be given a course of treatment as for a gastric ulcer, with general tonic and hygienic measures. One patient recovered after 10 silver lavages. The vomiting occurred during or soon after meals, and there was no pain. Traces of blood in the vomit after six months suggested the true diagnosis.

81. Periodical Neurasthenia.—Pulawski has witnessed 9 cases of this affection which should rather be called periodical exacerbations of a chronic neurasthenia. These exacerbations may last from one hour to a month or longer. They were characterized by depression in his experience. The prognosis seems to be less favorable than in ordinary neurasthenia.

86. Methylene Blue Test of Kidney Functions.—Landau found the results of this test unimportant in 24 subjects on whom it was applied. It can not be relied on alone as a criterion of the functional capacity of the kidneys. Another point to be borne in mind also is that the blue has to be transformed into chromogen, etc., before it can be eliminated through the kidneys. Consequently its elimination depends on this transforming function as much or more, possibly, as on the eliminating capacity of the kidney.

88. Influence of Alcohol on Circulation.—The writer's research fails to show any stimulating action of alcohol on the circulation of blood. The effect was rather to weaken the entire circulatory system.

89. Cultivation of Virus of Variola.—Ishigami announces that all attempts to inoculate animals with pure cultures of bacteria found in variolous and vaccine lymph, etc., proved negative. But he found that he could induce the production of typical vaccine pustules and protective power against variola by inoculating calves with a culture of the protozoa found in the epithelial cells of the vaccine pustules, lymph, etc. These sporozoa grow best on a culture medium made from the epithelial cells of an unvaccinated animal. He claims that the evidence is all in favor of the assumption that these sporozoa are the causal germs of variola.

90. Peculiar Neurosis in Japan.—Sakaki gives cuts showing the attitudes and general aspect of the subjects of this neurosis which is characterized by echolalia, echomimia and echokinesia with abnormal tendency to fright. There are no tics, grimaces nor obsessions. It is probably identical with the neurosis observed by Tokansky in Russia and described in the *Neur. Cbl.*, ix, p. 662.

91. Tuberculosis of the Pharynx.—Kanasugi regards the prognosis of this localization of tuberculosis as the most unfavorable of all, the primary more than the secondary. He eures into sound tissue and applies pure lactic acid.

92. Prophylaxis of Malaria in Formosa.—Koike states that the strict discipline of the Japanese army rendered possi-

ble the application of antimosquito measures on a large scale in this hotbed of malaria. The results, in his own words, were "so excellent as we scarcely heard ever." The barracks were screened and the beds provided with nets. The soldiers were obliged to be in the barracks half an hour before sunset, and the door was locked until half an hour after sunrise. No night duty was required of the corps to which these measures were applied. When any one was known to have been bitten by a mosquito he was removed to an isolated bed and net. The sentinels wore woolen trousers, gloves and mask. All bathing had to be done during the day. Not one of the 114 men in this corps contracted malaria, but a control corps, unprotected, had 32.59 per cent. affected, while 44.09 per cent. of the general force of nearly 700 men had malaria. The prophylactic measures were continued from September to February, and the soldiers were so impressed with the results that they have voluntarily continued the same precautions since, and other companies have begged to be thus protected.

93. Stored Rice and Beri-Beri.—This article asserts that beri-beri causes more than two-thirds of all deaths among the Chinese, and it is continually spreading among the Malays and Chinese. When the Malay grew and garnered his own rice he hulled the daily supply as needed, and beri-beri was unknown. But now imported rice is sold at such low prices that he prefers to buy it and save the trouble of cultivating rice. Beri-beri follows in the track of this imported and stored product.

95. Reducing Luxation of the Humerus.—Maarud has been much impressed with the value of Riedel's method for country practitioners as it dispenses with assistance and requires such brief narcosis.

96. Dispensing in Country Practice.—Bugge holds up to his country men the example of America in regard to the dispensing of medicine in tablets, etc., instead of the old-fashioned methods to which they still cling.

99. Reducing Luxatio Ant. Humeri.—Borchgrevink recommends a method of reducing this luxation based on the principle that when the arm is adducted, the upper wall of the capsule, and especially the coraco-humeral ligament is stretched, which prevents the head from rotating on its axis at that point and compels it to turn toward the cavity of the joint. As the arm is raised the coraco-humeral ligament and the edge of the rent in the capsule become relaxed, while the lower wall of the capsule is drawn taut, and this forces the head near or into its normal position. If it is not already entirely in place, inward rotation will bring it completely into its normal relations. The operation described is in four stages. The dislocated arm is first placed in extreme adduction. The upper arm is then slowly and cautiously twisted over and outward in this position, the elbow still at a right angle, until the front of the arm is in the frontal plane. While this outward rotation is maintained, the upper arm is raised in the sagittal plane to the extent that is possible without application of force. The arm is then rotated inward and the head of the humerus will be found in its cavity.

New Patents.

- Patents of interest to physicians, etc., November 4 and 11:
- 712634. Exercising apparatus. Richard Aronstein, Goldfield, Colo.
 - 712642. Device for administering anesthetics. Albert H. Bishop, Fort Dodge, Iowa.
 - 712643. Device for administering anesthetics. Albert H. Bishop, Fort Dodge, Iowa.
 - 712827. Exercising apparatus. George S. Maxwell, Jersey City, and G. White, Jr., Madison, N. J.
 - 712700. Bed pan. Christian W. Meinecke, Jersey City, N. J., and D. Hogan, New York.
 - 712711. Truss. Eugene J. O'Connor, Westport, New Zealand.
 - 712719. Optical instrument for testing the eyes. Gilbert B. Porter, St. Johns, Mich.
 - 713017. Syringe. Walter H. Pumphrey, New York.
 - 712720. Air bed. Fannie L. Richardson, Corinth, Miss.
 - 712979. Inhaler. Clarence W. Taylor, Sioux City, Iowa.
 - 712989. Electric cautery. Wm. E. Washburn, Cedar Rapids, Iowa.
 - 712746. Sterilizing apparatus. Adolf Watorck, Lemberg, Austria-Hungary.
 - 713395. Separating protoids from non-nitrogenous bodies. John Carstairs, Bradford, England.

713416. Invalid bed and commode. Wm. C. Feely, New York.
 713450. Hernial truss. Charles E. Kenyon, New York.
 713318. Suspensory bandage. Henry C. Lovis, New York.
 713234. Stopper for hot-water bags. Edward E. Menges, New Haven, Conn.
 713488. Vaccination shield. Nils Omsted and M. Iverson, Stoughton, Wis.
 713143. Adjustable pliable truss. Wm. Payne, London, Canada.
 713348. Retinoscope. Seth A. Rhodes, Chicago.
 713515. Apparatus for producing medicinal vapor or liquid from the smoke of green wood. Hamilton E. Smith, Philadelphia.
 723166. Obstetrical tractor. Emilian D. St. Cyr, Chicago.
 713530. Case for surgical instruments. Charles J. Tagliabue, Brooklyn.
 713365. Electromagnetic medical appliance. Francis H. Volley, Allegheny, Pa.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. Army, by orders from the Adjutant-General's Office, Washington, D. C., from November 15 to 20, inclusive.

Brewer, Isaac W., contract surgeon, U. S. A., now in this city, will proceed to Fort Huachuca, Ariz., and report in person to the commanding officer of that post for duty.

Cable, George W., contract surgeon, U. S. A., leave of absence granted in Special Order No. 177, Sept. 25, 1902, Department of Texas, is extended one month.

Dale, Frederick A., first lieutenant and asst.-surgeon, U. S. A., now at San Francisco, is relieved from further duty in the Division of the Philippines and from duty as transport surgeon on the transport *Sumner*, and will proceed to this city and report in person to the commanding officer of the U. S. General Hospital, Washington Barracks, for duty.

Eber, Albert H., captain and asst.-surgeon, U. S. Vols., is honorably discharged from the service of the United States by the Secretary of War, to take effect Dec. 31, 1902.

Eber, Albert H., captain and asst.-surgeon, U. S. Vols., is granted leave of absence to include Dec. 31, 1902.

Glennan, James D., surgeon U. S. A., is granted leave of absence for one month, to take effect on his relief from duty at the U. S. Military Academy.

Henderson, Albert B., first lieutenant, asst.-surgeon, U. S. A., is directed by the Secretary of War to report in person to Brigadier-General Frederick Funston, U. S. A., president of the Army Retiring Board, appointed to meet at Denver, at such time as he may designate, for examination by the board. On the completion of his examination Lieutenant Henderson will return to the place of receipt by him of this order.

Long, Stephen M., contract surgeon, U. S. A., is relieved from duty at Alcatraz Island, Cal., and will proceed to Fort Duchesne, Utah, and report in person to the commanding officer of that post for duty and by letter to the commanding general, Department of the Colorado.

Lyon, Palmer H., captain and asst.-surgeon, U. S. Vols., now serving in the Division of the Philippines, is honorably discharged by the Secretary of War, from the service of the United States, to take effect Dec. 31, 1902, his services being no longer required.

Madara, James W., captain and asst.-surgeon, U. S. Vols., now serving in the Division of the Philippines, is honorably discharged by the Secretary of War, from the service of the United States, to take effect Nov. 21, 1902, his services being no longer required.

Mabry, William C., contract surgeon, U. S. A., is granted six days' leave of absence.

McAndrew, Patrick H., first lieutenant and asst.-surgeon, U. S. A., is relieved from duty in the Division of the Philippines, and will proceed to San Francisco, and on arrival report by telegraph to the Adjutant-General of the Army for further orders.

McCaw, Walter D., major and surgeon, U. S. A., is detailed to represent the Medical Department of the Army at the General Sanitary Convention of American Republics, to meet in this city Dec. 2, 1902.

Rockhill, Edward P., first lieutenant and asst.-surgeon, U. S. A., is detailed as a member of the examining board convened at the Presidio of San Francisco, by Paragraph 9, Special Order No. 207, Sept. 9, 1902, vice Captain John S. Kulp, asst.-surgeon, hereby relieved.

Sinks, Edward D., contract surgeon, U. S. A., now at the U. S. General Hospital, Fort Bayard, N. M., will report in person to the commanding officer of that hospital for duty.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy, for the week ending Nov. 22, 1902:

Surgeon W. R. DuBose, ordered to the Navy Yard, League Island, Pa., for duty in connection with fitting out the *Maine*, and ordered to the *Maine*, when that vessel is placed in commission.

P. A. Surgeon T. W. Richards, detached from the bureau of medicine and surgery, Navy Department, and ordered to the *Arkansas*.

P. A. Surgeon E. O. Huntington, unexpired portion of sick leave revoked; ordered to the Naval Hospital, New York City, for treatment.

P. A. Surgeon W. H. Bucher, sick leave extending one month. Orders received from senior squadron commander of Asiatic Station.—P. A. Surgeon E. M. Shipp, detached from duty at Port Isabel, P. I., and ordered to the Naval Station, Cavite, P. I.

Asst.-Surgeon C. M. Oman, detached from the Naval Station, Cavite, P. I., and ordered to duty at Port Isabel, P. I.

Pharmacist C. McLarty, reported at the Navy Yard, Norfolk, Va., October 7.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Nov. 20, 1902:

Assistant Surgeon-General J. H. White, granted seven days' extension of leave of absence from November 24.

P. A. Surgeon L. E. Cofer, department letter granting leave of absence amended so that said leave shall be effective up to and including December 10.

P. A. Surgeon S. B. Grubbs, granted leave of absence for one month from December 8.

Asst.-Surgeon L. D. Fricks, relieved from duty at Savannah, Ga., and directed to proceed to Cape Fear Quarantine Station, and assume temporary command, relieving Asst.-Surgeon T. B. McClintic.

Asst.-Surgeon V. G. Heiser, to report to Assistant Surgeon-General L. L. Williams, chairman of Board of Examiners, for examination to determine his fitness for promotion to the grade of passed assistant-surgeon.

Asst.-Surgeon T. B. McClintic, on being relieved from duty at Cape Fear Quarantine Station, to proceed to Washington, D. C., and report to the director of the Hygienic Laboratory for duty.

Asst.-Surgeon W. A. Korn, leave of absence granted for 21 days from November 18, revoked.

Asst.-Surgeon T. D. Berry, department letter granting leave of absence on account of sickness, amended so that it shall be for one month and 27 days.

Asst.-Surgeon Edward Francis, to proceed to New York City for special temporary duty.

Asst.-Surgeon W. C. Rucker, relieved from duty at San Francisco, and directed to proceed to Reedy Island Quarantine Station and report to medical officer in command for duty and assignment to quarters.

A. A. Surgeon P. N. Barnesby, granted leave of absence for 21 days from November 10.

A. A. Surgeon L. P. Gibson, granted leave of absence for 10 days from Nov. 12, 1902, on account of sickness.

BOARDS CONVENED.
 Board convened at Washington, D. C., Nov. 18, 1902, for the examination of Asst.-Surgeon V. G. Heiser to :
 for promotion to the grade of passed assistant :
 the Board: Assistant Surgeon-General L. L. Williams, chairman; Assistant Surgeon-General G. T. Vaughan; Asst. Surgeon H. D. Geddings, recorder.

Board convened at the Marine-Hospital, San Francisco, Nov. 24, 1902, for the physical examination of a candidate for appointment as second assistant-engineer, Revenue Cutter Service. Detail for the Board: P. A. Surgeon W. G. Stimpson, chairman; P. A. Surgeon A. R. Thomas, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Nov. 22, 1902:

SMALLPOX—UNITED STATES.

California: San Francisco, Nov. 2-9, 2 cases; Stockton, Oct. 1-31, 3 cases; Stockton, Nov. 1-13, 1 case.

Colorado: Denver, Nov. 1-8, 7 cases.

Indiana: Indianapolis, Nov. 8-15, 2 cases.

Kansas: Wichita, Nov. 8-15, 1 case.

Louisiana: New Orleans, Nov. 8-15, 1 case.

Maine: Nov. 8-15, Biddeford, 3 cases; Portland, 1 case.

Massachusetts: Boston, Nov. 8-15, 20 cases, 2 deaths; Cambridge, Nov. 8-15, 1 case, 1 death; Marlboro, Nov. 1-15, 7 cases; Taunton, Nov. 8-15, 1 case; Weymouth, Nov. 8-15, 1 case; Worcester, Nov. 7-14, 1 case.

Michigan: Nov. 8-15, Detroit, 31 cases; Grand Rapids, 6 cases. New Hampshire: Nov. 8-15, Manchester, 2 cases; Nashua, 16 cases.

New Jersey: Nov. 8-15, Camden, 3 cases; Newark, 1 case.

New York: New York, Nov. 8-15, 2 cases.

Ohio: Cincinnati, Nov. 7-14, 3 cases; Cleveland, Nov. 8-15, 21 cases, 4 deaths; Dayton, Nov. 8-15, 3 cases; Youngstown, Nov. 1-8, 1 case.

Pennsylvania: Altoona, Nov. 10-17, 3 cases; Erie, Nov. 8-15, 4 cases; Johnstown, Nov. 8-15, 5 cases; McKeesport, Nov. 8-15, 4 cases; Philadelphia, Nov. 8-15, 3 cases; Pittsburgh, Nov. 8-15, 25 cases, 7 deaths.

Utah: Salt Lake City, Nov. 8-15, 1 case.

Wisconsin: Milwaukee, Nov. 8-15, 10 cases.

SMALLPOX—FOREIGN.

Barbadoes: Oct. 12-25, 146 cases.

Austria: Prague, Oct. 25-Nov. 1, 14 cases.

France: La Rochelle, Oct. 19-26, 1 death; Rheims, Oct. 10-Nov.

2, 1 case, 1 death; Roubaix, Oct. 1-31, 1 death.

Great Britain: Leeds, Oct. 25-Nov. 8, 3 cases; Liverpool, Oct. 25-

Nov. 1, 3 cases; Manchester, Oct. 25-Nov. 1, 1 case.

India: Bombay, Oct. 7-21, 6 cases; Calcutta, Sept. 27-Oct. 18, 1 case; Madras, Oct. 4-10, 1 death.

Italy: Milan, Sept. 1-30, 1 case; Palermo, Oct. 18-Nov. 1, 2 cases.

Russia: Moscow, Oct. 18-25, 1 death.

Straits Settlements: Singapore, Sept. 20-27, 6 deaths.

Turkey: Constantinople, Oct. 19-Nov. 2, 2 cases.

YELLOW FEVER.

Colombia: Panama, Nov. 3-10, 4 cases.

Mexico: Nov. 1-8, Coatzacoalcas, 2 cases, 1 death; Tampico, 7

deaths; Vera Cruz, 10 cases, 6 deaths.

CHOLERA—INSULAR.

Philippine Islands: Sept. 21-27, Manila, 43 cases, 36 deaths;

Provinces, 5,583 cases, 3,560 deaths.

CHOLERA—FOREIGN.

China: New Chwang, Sept. 13-20, 25 cases, 25 deaths.

India: Bombay, Oct. 7-21, 2 deaths; Calcutta, Sept. 27-Oct. 18,

47 deaths.

Japan: Kobe, Oct. 11-18, 24 cases, 12 deaths; Nagasaki, Oct. 11-

20, 61 cases, 41 deaths.

Java: Batavia, Sept. 27-Oct. 4, 42 cases, 38 deaths.

Straits Settlements: Singapore, Sept. 21-27, 22 deaths.

PLAGUE—FOREIGN.

China: Hongkong, Oct. 4-11, 1 case, 1 death.

India: Bombay, Oct. 7-21, 142 deaths; Calcutta, Sept. 27-Oct. 18,

25 deaths; Karachi, Oct. 12-19, 13 cases, 9 deaths.

The Journal of the American Medical Association

CHICAGO, ILLINOIS, DECEMBER 13, 1902.

No. 24.

Address.

A REVIEW OF CURRENT PEDIATRIC LITERATURE.

CHAIRMAN'S ADDRESS, DELIVERED BEFORE THE SECTION ON
DISEASES OF CHILDREN, AT THE FIFTY-THIRD ANNUAL
MEETING OF THE AMERICAN MEDICAL ASSOCIATION,
AT SARATOGA SPRINGS, N. Y.,
JUNE 10-13, 1902.

H. M. McCLANAHAN, A.M., M.D.
OMAHA.

For the honor of being elected Chairman of this Section I am deeply grateful, and again thank you most sincerely. It has been my earnest effort during the year to interest members in this Section and enlarge its sphere of influence commensurate with its importance. I am deeply grateful to the members of the Executive Committee for their valuable advice and timely suggestions.

It is with pleasure that I acknowledge my indebtedness to the Secretary, Dr. Frank X. Walls. I thank him most sincerely for his hearty co-operation and many valuable suggestions. The program now before you is sufficient evidence that he has discharged the duties of his office faithfully and with ability.

RECOMMENDATIONS.

The following recommendations are offered for your consideration: First. I renew the recommendation Dr. Tuley made in 1899, that a committee on necrology be appointed, and suggest that this committee consist of three members appointed for one, two and three years respectively. This will make the committee continuous and some of the members will be constantly in touch with the interests of the Section. It is only just to those who have contributed to the welfare of this Section that when their life's work is ended some recognition be accorded to their memory. Such recognition would also be an incentive to members to take an active part in the work of the Section.

Second. I believe it would increase the interest and welfare of the Section if we had a permanent list of members, and suggest that all those who are members of the American Medical Association, and who have registered in this Section for two consecutive years, have their names and addresses printed in the volume of the annual transactions. This would encourage members to register in this Section, and I am certain it would be a great benefit to the officers of the Section. It would relieve them of the humiliation of inviting those to contribute who, *not being members of the American Medical Association*, are not eligible to participate in its deliberation.

Third. It would certainly enhance the welfare of the

Section if there were more of a community of interest between those who attend its meetings. As it is, we meet for three or four days in the year and then return to our homes in widely dispersed parts of the country. Our private work so fully occupies our time that no consideration is given to the Section until the next meeting. If some work could be carried on during this interim, whereby the attention of the members would be called to the affairs of the Section, it would certainly be advantageous. To this end I would recommend that a committee be appointed whose duty it would be to conduct a collective investigation on certain scientific subjects. You are all aware of the splendid results accomplished by the American Pediatric Society; that our knowledge of *scorbutus* and the use of antitoxin have been largely enhanced as a result of their labors. Similar investigation conducted by members of this Section would in no way be antagonistic to the work of that splendid organization. In addition to the valuable information obtained, such work would have the distinct advantage of centering the interest of the members in this Section. The serious objection that might be urged is that the work would involve a considerable outlay of money. However, as the end would justify the means, I have no doubt that some way of providing the necessary funds could be devised.

INDEX OF CURRENT PEDIATRIC LITERATURE.

In compliance with Section 4, Chapter IX, of the Constitution, I present briefly for your consideration a short review of the current pediatric literature. The source of my information in looking up this literature was the index medicus published in the *Medical Review of Reviews*. There were many papers in other departments, dealing in a large measure with *pediatric subjects*. These I have not taken into account in my review. There have appeared during the year 477 articles in medical journals published in this country alone on distinctly pediatric subjects. Of this number I have read 200 articles in full; of the remaining 277 I have read abstracts as they appeared during the year in a number of the leading medical journals. These articles I have classified as carefully as possible.

GASTROINTESTINAL DISEASES.

On diseases of the digestive organs there were 62 papers, a large number dealing with summer diarrheas. That which impressed me most in this series was the practicable unanimity of the authors, both as to the cause and treatment of this important group of maladies. Some of these papers were valuable because they gave results of treatment in a large series of cases. The rise and progress in our knowledge of intestinal infections is graphically illustrated in the presidential address of Dr. Booker before the American Pediatric Society. It is

remarkable, but true, that almost our entire knowledge has been acquired within the last twenty-five years. As a result of the clearer knowledge and greater interest in this class of diseases, thousands of lives are now annually saved. The principles of treatment are now so well established that they have become a common property of our profession. Indeed, the means of prevention are now so largely known among the laity that these diseases are becoming less frequent. On the subject of treatment I could not fail to note that less dependence is placed on the use of drugs than in former years. It was apparent in the entire series of papers. It is also evident that greater reliance is placed on the application of hydrotherapy in the treatment of this entire group. The various methods of applying water and the objects to be attained in its use were clearly set forth in some of the papers.

There were five papers on the subject of appendicitis. The youngest case reported was that of an infant of three months. It is doubtless true that appendicitis is more rare in infants than in children or adults. The possibility of its occurring even in the very young should not escape our attention. Dilatation of the stomach in bottle-fed infants was alluded to in several articles.

That this condition is the result of food lacking in nutritive elements is well established. There were papers on constipation, intestinal sapremia, vomiting and indigestion. It is coming to be more fully realized that indigestion is usually a result of improper feeding.

INFANT FEEDING.

On the important subject of infant feeding there were 28 articles. Some of these were of the highest order. The year's literature on this subject is most satisfactory, showing important advancement in our knowledge and a wider appreciation of the importance of careful scientific study of this subject. I am convinced that erroneous impressions prevail among many members of our profession concerning the real knowledge on this subject. There are those who believe that infant feeding is in a chaotic state. That the authorities are widely at variance among themselves, and that consequently it is not worth while to give the subject careful study. It is unfortunate that such an impression prevails. It would have been well if every physician had read this series of articles, because a careful reading of them would have convinced any candid physician that such an impression is entirely erroneous. The differences of opinion are on minor matters, and are only such as naturally obtain among independent, original investigators, and do not affect the most important principles. This subject is so important that at the expense of mentioning matters entirely familiar to you all I will briefly state the important phases of the subject on which there is an entire unanimity of sentiment, as established by this series of papers:

1. Cow's milk is now recognized as the universal substitute for human milk.

2. The necessity of procuring more wholesome milk supply, including the care, feeding and housing of the cow, cleanliness in milking, bottling and transporting of the milk.

3. That contaminated milk can not be made pure and wholesome by any process known to science. This important fact, now generally recognized by original investigators, is not duly appreciated by many physicians.

4. That infants differ in their ability to digest food, and that each one requires special study. It is just here

that the question of judgment and accurate knowledge is essential to success.

5. That milk should be modified in order to adopt it to the needs of the infant. On details of modification there are differences of opinion, but these differences are on minor matters. I could not fail to note that even in these minor details there was a greater unanimity of opinion than I had supposed. I think the false impressions on our real knowledge of this subject are the results of the fact that some discussions on it have been sharp and acrid, but I repeat that these discussions were not on well-established principles, but on minor details. The advance in this field of pediatrics within the last ten years is nothing less than marvelous, and should be highly gratifying to all those who are giving the subject careful attention. It is probably only just to state that the advance has been largely the result of the work of investigators of our own country. I venture the assertion that in no field of medicine or surgery have the results of increased knowledge been of greater benefit to mankind in the actual saving of life than in the domain of infant feeding.

In view of the fact that during the year there was almost no literature on the subject of breast feeding, the question suggested itself to me whether or not this subject was being neglected. In improving the method of bottle feeding, are we not in danger of neglecting the subject of normal lactation? The responsibility of the physician in this matter is very great. His counsel is usually sought and his advice generally accepted. The important question suggests itself: What is his moral duty? This question is rightly within the province of this Section. I leave it with you for further consideration.

THE INFECTIOUS DISEASES.

Infectious diseases received consideration in 32 articles. Forty-five of these were on the subject of diphtheria. The knowledge of the profession as a whole on this disease is probably more complete than on any of the other acute diseases. I believe this is due to the comparative large volume of current literature on the subject. The papers during the year have not, as far as I could discover, developed anything new, either in pathology or treatment, but rather have made the existing knowledge more clear and widely disseminated, and have established the specific treatment more permanently.

On the treatment of diphtheria by antitoxin there is an almost unanimity of sentiment. I found but two arguments against the efficacy of this remedy. They were, first, that many cases were now diagnosed as diphtheria that formerly passed under some other name, and, second, that diphtheria is a milder disease than in former years. In view, however, of the experience of a large number of observers who have treated the disease for many years, these arguments have very little weight. I did not find in all these papers the record of a single death attributed to the use of this remedy. Two most enthusiastic articles on the efficacy of antitoxin were in homeopathic journals. This is certainly a triumph for rational scientific medicine and heralds the dawn of better days. The perusal of these articles demonstrates the following facts: The use of the remedy at the earliest possible moment, its repetition within a few hours, if appreciable benefit is not received, and the injection of larger doses than were recommended a few years ago.

Frequently I find that the term membranous croup is still implied to designate a condition other than diphtheria. It is unfortunate that there are physicians

still in active practice who fail to realize that acute laryngeal stenosis is usually diphtheritic in character. At this day, in the light of modern science, it is almost criminal that physicians should permit children to die of suffocation without giving them the benefit of antitoxin.

Scarlet fever received consideration in 18 papers. The most important additions to current literature of this disease were the contributions of Dr. Class of Chicago. It seems probable that the organism causing this disease has been isolated. At any rate, his work is valuable and is worthy of emulation. The diagnosis of the milder type of scarlet fever received some attention. These cases require careful scrutiny. A thorough examination of the throat is important in differentiating milder scarlet fever from cutaneous rashes due to other causes. There are a few reports of the use of serum in septic cases. There was one able paper on the importance of the careful treatment of the nasopharynx in the cases with severe angina. Middle-ear complications are now generally recognized, but the operation of paracentesis does not receive sufficient consideration. The relation of scarlet fever to diphtheria is still under discussion. The weight of opinion is that the membranous sore throat of scarlet fever is seldom due to the diphtheria germ. Reports indicate that scarlatinal nephritis is usually the sequel of mild cases of the disease.

There were 14 papers on the subject of measles. I noted the frequency with which measles is associated with some other acute disease. There can be no question of the value of the Koplik spots in diagnosis of measles in the prodromal stage. I have recently had the opportunity of observing measles during the recent epidemic in my city, and had frequent opportunities of making the proper diagnosis two or three days before the appearance of the eruption. The most frequent and serious complication of measles is catarrhal pneumonia. Laryngitis, causing severe stenosis, was several times mentioned, and, indeed, some cases reported. Otitis media as a complication of measles was several times mentioned. The importance of this complication is not duly appreciated. A few cases of severe nasal hemorrhage were mentioned. The most important fact brought out in these papers on the treatment of this disease was the necessity of care during the prodromal stage.

There were eight papers treating of the subject of whooping cough. The frequency of the association of whooping cough with measles was noted in more than one paper. The mortality in whooping cough is in direct proportion to the age. I noted the report of one death due to cerebral hemorrhage, two cases of subconjunctival hemorrhage and one case of hemorrhage from the ear. Of the remedies used in controlling this disease antipyrin received the most consideration. In one article a series of cases were reported as being controlled by the introduction of carbonic acid gas into the bowel. The results of this treatment were most gratifying. The number of cases, however, was not sufficiently large to admit of any positive conclusion being drawn.

There were three articles on chicken-pox and two on smallpox. These articles were valuable in demonstrating the distinction between these two diseases. Both papers were based on the study of a large number of cases in institutions where careful observations were possible. In both reports the greater number of the children had previously had chicken-pox. The period of incubation was accurately determined in a number of

cases, the length of this period being three days. The prodromal symptoms of smallpox, as noted in these papers, did not differ from those in adults. The subject of vaccination received almost no attention. In view of the prejudice among the laity against vaccination the importance of care in this operation is very great. I fear that much of the prejudice is the result of carelessness among physicians.

RESPIRATORY DISEASES.

On diseases of the respiratory tract, including pneumonia, bronchitis, asthma and empyema, there were 31 articles. It is manifest from this series of papers that secondary pneumonia in infants is the most serious and fatal disease of childhood. The literature on the bacteriology of pneumonia was meager and confirms what is already known that it is usually a mixed infection. Further research in this direction is needed. The diagnosis of catarrhal pneumonia is often difficult. Dependence must be placed on the general symptoms as well as the physical signs. On the treatment of this important disease the following statements can be safely made as conveying a sentiment of the writer: Supporting treatment, including the use of alcoholic stimulants and careful attention to the diet. The tendency to the use of local applications is less than in former years. The remedies most frequently recommended are strychnia, digitalis and steam inhalation. Judging from the literature empyema is frequently overlooked. In any pneumonia going beyond the fourth week careful examination of the chest should be made for a possible empyema. When this condition is present, prompt surgical treatment is always indicated. As to the cause of asthma two theories are advanced, one, that it is a neurotic element, the other is that it is due to uric acid diathesis.

TUBERCULOSIS.

On the subject of general tuberculosis there were 17 articles, not including those on the surgical treatment of tubercular affections. The most valuable papers of this group were those treating on the early symptoms. It seems entirely probable that there is a condition of ill health preceding the gross manifestations of tubercular lesions, and that it should be the effort of the physician to recognize this condition. The importance of glandular tuberculosis and its careful diagnosis is not as yet fully appreciated. The question of the infections of the infant by means of cow's milk is yet an open question. The drugs most frequently recommended were guaiacol and iron. On the general treatment, the important factors are the improvement of nutrition by means of proper foods, fresh air and sunshine.

MALNUTRITION DYSCRASIAS.

On the general subject of diseases of nutrition there were the following: Rachitis, 7; scorbutus, 13; marasmus, 6; cretinism, 5; anemia, 4. Our literature on this important group of diseases is meager. There is here a field for missionary work. Without doubt many cases of scorbutus, for want of more widely diffused knowledge, go astray under some other name. A correct diagnosis is more important than in most diseases of infancy, because of the fact of its prompt response to proper treatment. The results of the splendid work of the American Pediatric Society on these diseases are not as generally known as they should be. There were some good papers on the early symptoms of rachitis. It is entirely probable that this condition is caused by foods lacking in fats. The influence of the race as a predisposed cause is well established. Cretinism deserves further study at

your hands. A collective report on this condition would be of very great value.

TYPHOID FEVER.

There were 11 articles on this subject of typhoid fever in children. The literature on this disease is interesting and instructive and includes a considerable amount of original work. The value of the Widal test in the diagnosis of typhoid fever is valuable and its employment in a large number of cases will yield practical results. The conclusion drawn from this literature is that typhoid fever is mild in the infant and that there are fewer complications, consequently the prognosis is better than in the adult.

THE BLOOD AND THE NERVOUS SYSTEM.

On the diseases of the nervous system there were 25 articles. The strictly pediatric literature on this important subject impressed me less favorably than any of the other groups. This is a department of pediatrics requiring careful study and more accurate observation. The limited number of papers on so important a disease as chorea will indicate that the subject does not receive the attention its importance demands. The most valuable lesson derived from this series of papers was the relation between anemia and nervous diseases. In a paper on the subject of hydrocephalus I was impressed with the treatment suggested. This consists in the gradual withdrawal of the fluid and at the same time the introduction of sterilized air. Any treatment that offers a hope of benefit in this condition is worthy of further trial.

There were six articles on the blood. These were, without exception, valuable papers. I call attention to this series because investigations in this line indicate a promising field. As far as I could ascertain the number of examinations of the blood in health and disease is yet too limited to permit of positive conclusions being drawn. This is an inviting field of research for the young physician with a modern education. A large series of careful observations will necessarily lead to the accumulation of practical knowledge.

OTHER DISEASES.

On diseases of the newly born there were 31 articles, including papers on ophthalmia, icterus, hemorrhage, tetanus, sepsis and developmental defects. This was an interesting group of papers on a subject receiving scant consideration from many in our profession. I am convinced that a careful investigation of the subject of causes of death of the newly born would yield practical results.

There were 25 articles on diseases of the genito-urinary system. The most striking fact ascertained from these series of papers was that the operation of circumcision is coming more and more into favor. There were a number of papers on enuresis. I am convinced that the treatment of this condition is in many cases unsatisfactory, and that it is a symptom indicating some general defect, rather than any local lesion.

Surgical pediatrics received consideration in 25 articles. This is a small volume of literature when we consider the number of operations indicated in infancy. There were two interesting papers on the subject of spinal anesthesia. The objection to this method of anesthesia in adults is that the patient is conscious of what is going on about him, and, while relieved of physical suffering, he endures mental anguish. This objection does not have the same force in infancy. Again, there were a few cases reported of infants suffering from pneumonia, in whom general anesthesia was contrain-

dicated, and who were operated on safely and without pain by means of spinal anesthesia. This important and humane field of pediatrics is well worthy the careful study and attention of physicians.

There were 84 articles on a large number of miscellaneous subjects. For lack of time I shall not make any comment on this group.

THE IMPORTANCE OF PEDIATRIC LITERATURE.

Viewing this mass of current pediatric literature as a whole it indicates growth and increased interest in the diseases of children. However, it is my deliberate judgment that it is not up to the standard of the current literature in other branches of medicine. Current medical literature is exceedingly important for many reasons especially because it has more influence in molding public sentiment than standard text-book literature. The busy physician will read his medical journal when for want of time he will not study standard text-books. It is essential, therefore, that current medical literature shall be of the highest order and shall embody the best thought of the profession. Pediatric literature covers a wide field; it touches all branches of medicine, both scientific and practical. It is of equal importance from every point of view with the literature of any other branch of medicine. On those interested in pediatrics rests the responsibility for the quality of the literature. I therefore urge on the members of this Section the necessity of recognizing their duty in this respect. Your sense of pride as well as your desire to be useful in your profession require that you do your part in extending and enlarging the volume and improving the quality of current pediatric literature, so that it shall at least equal, if not excel, the current literature in other branches, in literary excellence, in clinical observation and in original research.

Original Articles.

A CRITICAL REVIEW OF 416 CASES OF APPENDICITIS

OPERATED ON IN THE GERMAN HOSPITAL, PHILADELPHIA, IN 1901.*

JOHN B. DEEVER, M.D., AND GEO. G. ROSS, M.D.
PHILADELPHIA.

GENERAL STATISTICS.

There were operated on during the year 1901 in the German Hospital and the children's wards of the Mary J. Drexel Home 416 cases of appendicitis.¹ Of this number there were 279 acute cases, of which 238 were adults and 41 children, under twelve years of age.

There were operated on 137 cases of chronic inflammation of the appendix, of which 134 were adults and 3 children. The mortality in acute cases in adults was 37, or 15.5 per cent.; in children there were 6 deaths, or 14.6 per cent.: making a total death rate in acute cases operated on of 15.3 per cent. This list includes one child who died three months after operation from purulent peritonitis and septic nephritis with uremia; one who died on the table of ether shock, having had general purulent peritonitis at time of operation. The mortality statistics will be considered later and for the present we will take up a consideration of the entire number of cases.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard.
1. The statistics of this paper were compiled by Dr. Geo. P. Müller, house surgeon German Hospital.

There were 137 chronic cases with one death, a mortality of 0.7 per cent. This death was the result of an acute intestinal obstruction. The obstruction was caused by a loop of small bowel becoming engaged in a rent in the mesentery. These figures speak for themselves and demonstrate beyond question the possibility of removing the appendix at the opportune time with practically no mortality.

ETIOLOGIC FACTORS.

Sex.—In adults, in the acute cases, males were the subject of the disease in 145 cases and females in 83 cases. In children there were 31 males and 10 females.

Age.—The ages of patients at the time of attack were as follows: 1 to 10 years, 23 cases; 10 to 20, 72; 20 to 30, 102; 30 to 40, 49; 40 to 50, 21; 50 to 60, 8; 70 to 80, 1; not noted, 3, the youngest patient being 4 years and the oldest 77.

Gastro-Intestinal Disturbances.—In 86 cases there was a history of some digestive disturbance, usually dyspepsia, prior to the initial attack of appendicitis. Constipation occurred in 162 cases, diarrhea in 36, normal bowels in 67, not noted in 13, vomiting in 191, nausea in 15, absence of nausea or vomiting in 62, not noted in 12.

COMPLICATIONS.

Tumor.—A mass in the right iliac fossa was demonstrated clinically in 104 cases.

Sepsis.—Pus infection with abscess formation was encountered in 174 cases as follows: Post-cecal, adults 29, children 12; right iliac fossa, adults 35, children 1; pelvis, adults 20, children 14; and in the following found only in adults: outer side of cecum 21, free pus (not confined) 18, in appendix only 13, to median side of cecum 2, free cloudy serum 4, sub-hepatic 3, multiple 1, extraperitoneal 1.

Adhesions.—These were encountered in 189 instances, 155 adults, 34 children.

Necrosis.—This occurred as follows: Appendix, adults 75 cases, children 31; cecum only, adults 4, children 1; small bowel, adults 1; cecum and appendix, adults 7; mucous membrane of appendix alone, 4; semi-gangrenous condition of appendix and cecum, 22; total, 145 cases.

Perforation.—There was perforation as follows: Appendix, adults 41, children 32; cecum, adults 3; appendix sloughed from cecum, adults 8; total, 84 cases.

Attention is drawn to the fact that in 299 acute cases pus was encountered 174 times; necrosis of the appendix, cecum or small bowel, 145 times, and perforation 84 times. Are not these figures a convincing argument against delay in operating on this really terrible disease? If they are not, then stop and think that 15.3 per cent. died as a result of a continuance of the acute inflammation while 99.3 per cent. of those operated on at a time of election recovered, not only from future attacks, but from the disease.

Peritonitis.—Local, adults 104 cases, children 4; general, adults 25, children 23. In 11 adults the general infection was purulent and all of these died. It will thus be seen that a general infection, while much more common in children than in adults, is not nearly so fatal, probably due to a higher resisting power of children to peritoneal infection, a fact that is true in other forms of infection in other localities.

Drainage.—In 154 cases drainage was used, gauze wicks, glass tubes and rubber tubes being the three methods employed.

Appendectomy.—The appendix was removed in 269

cases, was not removed in 7, and had sloughed off from the cecum in 3.

Intestinal Obstruction.—Post-operative obstruction occurred in 10 cases, of which 4 recovered from a second operation and 6 died. In 9 of the 10 cases the obstruction was due to the adhesive inflammation in the right iliac fossa, which continued to be active after the removal of the organ and the breaking up of the existing adhesions. In the tenth case it was due to accidental causes; the wound, which had been closed with layer sutures of catgut, was forced open by a violent fit of coughing. While attempting to replace the protruding bowel, infection was introduced and the patient promptly developed peritonitis and obstruction, causing his death. It is a very fatal accident, as these figures show 6 of the 10 dying as a direct result; a mortality of 60 per cent. The condition was recognized very early in every instance and operation instituted at once, but with the above result. These facts lead us to believe that the early operation in the primary attack is, after all, the safest procedure.

Fistula.—Fecal fistula appeared in 11 cases, 3 on the fifth day, 1 on the sixth day, 1 on the seventh day, 1 on the thirteenth day, 1 on the seventeenth day, and in 4 the day of appearance was not noted. Four cases closed spontaneously, one was operated on and recovered, 6 cases left the hospital with fistula, one of which returned during January, 1902, was operated on and discharged from the hospital, recovered. All of these were in late cases, where the intensity of the highly destructive inflammation resulted in gangrene of the cecum or neighboring bowel and made the false passage inevitable. In one case, a man operated on late in the attack, there was an opening in the posterior wall of the cecum, the edges of which and a surrounding area of cecal wall one inch in diameter were gangrenous and would not hold the stitches. The man, however, did not develop a fistula, evidently due to the fact that the opening, which was in the posterior wall of the cecum, came in contact with the posterior layer of the peritoneum covering the right iliac fossa and there became adherent. That four of the cases healed spontaneously can hardly be offered as a valid reason for waiting until the structures involved in the inflammatory area are in such a state of pathologic decomposition that unhappy results become almost inevitable.

TIME OF OPERATION.

Of the cases operated on, a large percentage gave a history of being admitted during the first attack; however, over 80 gave a history of attacks of indigestion or more or less persistent digestive disturbances, with constipation or irregularity of the bowels associated with pain. It is impossible to arrive at a definite knowledge of the importance of these intestinal troubles, and just what relationship they bear to attacks of appendicitis. It is fair to presume, however, that a good proportion, if not the majority, have had previous attacks, probably mild and transitory, but none the less real attacks. This presumption is based on the fact that patients and frequently family physicians do not recognize early attacks, particularly if they be mild and transitory in character, passing them by as attacks of bilious colic, dyspepsia, etc.

Time Between Onset and Operation.—The time elapsed between onset of attack (acute) and time of operation is as follows: 5 hours in 2 cases, 8 in 2 cases, 12 in 5 cases, 14 in 1 case, 16 in 2 cases, 18 in 2 cases,

20 in 1 case, 24 in 18 cases, 30 in 1 case, 36 in 4 cases, 40 in 35 cases, 50 in 1 case, 3 days in 29 cases, 4 in 25 cases, 5 in 18 cases, 6 in 12 cases, 7 in 29 cases, 8 in 9 cases, 9 in 5 cases, 10 in 13 cases, 11 in 5 cases, 12 in 4 cases, 14 in 24 cases, 19 in 1 case, 3 weeks in 11 cases, 7 in 1 case, 8 in 1 case, 10 in 1 case, 6 months in 1 case.

MORTALITY STATISTICS.

There were thirty-seven deaths from acute appendicitis in adults during 1901, a mortality of 15.5 per cent.; 34 were males and 3 were females. The age varied from 14 to 77 years, averaging 34 years. In decades there were from 14 to 25 years 15 cases, 25 to 40 years 11 cases, and 40 to 77 years 11.

Previous Attacks.—11 cases were in the initial attack, 7 had 1 previous attack, 2 had 2 previous, 4 had 3 previous, 10 had several previous, and in 3 cases the number of attacks was not stated.

Of the fatal cases which were operated on in the first attack there are several important facts to be noticed. In one case the death was attributed to the accidental breaking open of the wound and subsequent intestinal obstruction and peritonitis. In another case, operated on within twenty-four hours, there existed at the time of operation a general purulent peritonitis. The other cases had been ill with the disease from forty-eight hours to two weeks. All but one had abscess and most of them necrosis. The one exception was the patient who died on the sixteenth day after operation of uremia. Another had in addition to an appendiceal abscess, a carcinoma of the cecum.

PREVIOUS DISEASE AND FAMILY HISTORY.

In two cases there was a family history of phthisis. Case 14 had scarlet fever one year previous to the appendicitis attack, accompanied by nephritis. Ten days after operation she developed uremia and died on the sixteenth day after operation. Case 32 had performed several abortions on herself, each time with severe systemic disturbances, the last one was three days before the onset of the appendicitis attack. Case 36 had all the exanthemata of childhood, including scarlet fever. He had enteric fever and influenza in early adult life. He died of sepsis after a hard fight, fourteen days after operation.

Urine.—Three patients, on admission, were found to have a well-marked nephritis, though none of these died of uremia. Nearly all the cases showed traces of albumin, including three cases dying of nephritis. Every case gave albumin and casts after etherization.

Bowels.—Previous constipation is mentioned in 22 cases and diarrhea in 2 cases, just preceding the attack and followed by constipation after the onset. The bowels were regular in 7 cases.

Stomach.—Chronic dyspepsia is noted in 30 per cent. of the cases.

SUMMARY OF SYMPTOMS.

Admission to Hospital.—The patients were admitted from 8 hours to 14 days after the onset of the last attack, averaging 6 days, as follows: Within 24 hours 3 cases, after 2 days 5 cases, after 3 days 5, after 4 days 5, after 5 days 1, after 6 days 4, after 7 days 4, after 8 days 2, after 10 days 2, after 11 days 1, after 12 days 1, after 14 days 4.

Temperature and Pulse.—The temperature on admission varied from 97.4 to 102.6 and averaged 100.2. The pulse was 76 to 162, averaging 97.

Nausea.—Vomiting was present in 25 cases, nausea only present in 10 cases, no nausea nor vomiting present in 2 cases.

Pain.—The pain began either as a sharp colicky pain about the umbilicus or as a dull ache in the epigastrium, becoming in a few hours either general (20 cases), or localized to the right iliac fossa (17 cases).

Tenderness.—This was present in every case and usually exquisite in character.

Rigidity.—This was noted on both sides in 22 cases, on right side only, in 15 cases.

Tympanites.—This was present in 14 cases, absent in 23 cases.

Tumor.—A well-defined mass was noted clinically in 18 cases, and a slight tumor in 3, in every case confirmed by operation. Sixteen cases failed to show the presence of a mass clinically; in 6 of these general purulent peritonitis existed with marked tympanites, and in 2 cases the abscess was in the pelvis.

OPERATIVE DETAILS.

Time of Operation.—23 cases were operated on on the day of admission, 12 cases on the day after admission, 1 on the fourth day after and 1 on the seventh day.

Anesthetic.—In all cases ether was used as the anesthetic and the time of operation varied from several minutes in two cases, where the abscess cavity was merely opened and drained, owing to the poor condition of the patient, to fifty minutes. The average time was from 25 to 30 minutes.

Incision.—The incision was made through the right rectus in cases where no tumor mass was determined and to the outer side of the tumor, when that was detected. The incision was always large enough to work with ease. Edema of abdominal walls was encountered six times.

Adhesions.—In 33 cases the appendix or the cecum were bound either together, to the abscess wall or to the right iliac fossa in a mass of adhesions. In two cases there were no adhesions.

Condition of the Belly Cavity.—In 11 cases there was a general purulent peritonitis, in 9 of which the appendix was perforated, necrotic and gangrenous and in which the small bowel was the subject of exudative peritonitis. In the others the appendix was highly inflamed, but with no perforation, and an abdomen full of sero-pus, evidently a migration of the infecting organism through the diseased wall of the appendix. In 11 cases there existed a large localized collection of pus in the right iliac fossa, well walled off in most instances by a thick exudate, tangled omentum, cecum and small bowel, and containing foul greenish pus. In these abscesses the appendix in 5 cases floated, necrosed from the cecum. In 4 cases the appendix was gangrenous, usually perforated. In 2 cases the appendix was not searched for—merely opening and draining the abscess. In all cases there was more or less necrosis of the cecum. Whether there was general infection was not determined at operation.

In 5 cases there not only existed a localized abscess in the right iliac fossa, but also a collection in the pelvis and with the appendix either on the brim or in the pelvis, and in an ulcerated and semi-gangrenous condition with a perforation in 3 cases. In 7 cases there existed a small collection of pus about the appendix in the right iliac fossa with a perforated appendix in 2 cases. The other cases showed a highly inflamed appendix with necrosis of the mucous membrane.

Three cases were free from abscess formation: Case 3, with a coincident carcinoma of the cecum; Case 14, with an acute interstitial appendicitis; and Case 34, with an acute catarrhal inflammation of appendix. These cases, with the cause of death, are discussed later.

Methods of Appendicectomy.—In 35 cases the appendix was removed either by ligation or by cutting it off at the cecum, except in the 5 cases with entire necrosis of the cecal end of the appendix. In these cases an attempt was made to close the cecum with Lembert sutures and in one a fecal fistula was encouraged owing to the extensive sloughing of the head of the cecum.

Drainage.—Thirty-three cases were drained, 17 by use of a glass tube into the pelvis and from one to eight pieces of iodoform gauze either in the coffer dam arrangement, or as wicks to drain the pelvis, abscess cavity or appendix stump. In some cases of general infection one or more pieces of gauze were placed across the abdomen. In 2 cases a loin incision was also made and rubber counter drainage introduced. Four cases were not drained. Cases 3, 14 and 34 were clean and were sewed up in tier suture, the first two with silk and Case 34 with catgut. Case 30 was one of general peritonitis, but there was no free pus, merely a lusterless peritoneum with a turbid, odorless sero-pus in the pelvis and the appendicitis was of but eight hours' duration. Eight of the cases of general peritonitis were freely irrigated.

DEATH AND CAUSES.

Time of Death.—Death took place on an average of 5.4 days after operation, excepting the last two cases, as follows: Within 24 hours 3 cases, on the second day 2, on the third day 10, on the fourth day 5, on the fifth day 2, on the sixth day 3, on the seventh day 1, on the eighth day 3, on the ninth day 2, on the tenth day 1, on the fourteenth day 1, on the sixteenth day 2, on the forty-first day 1, on the forty-third day 1.

When we review the clinical histories, the findings at the operating table and the results of a partial postmortem of the 37 deaths which have been analyzed in the preceding paragraphs we find four causes for the death of these patients.

Peritonitis.—First and foremost stands that dreadful disease, peritonitis, by far the most frequent complication of appendicitis. Thirty-two cases or 86 per cent. of these deaths were due to that infection; and as general purulent peritonitis, in our experience, is almost invariably fatal, these 11 cases were beyond surgical aid when admitted to the hospital. Three of these were of the fulminating type, were promptly recognized and sent in for operation within twenty-four hours of the onset, but not one was suffering from an initial attack—two, four and five previous onslaughts of appendicitis tells the story of the fatal ending of these cases. They had "recovered" from the early attacks. Of the other 8 cases, 4 were in the initial attack, but after the use of calomel, poultices and careful deliberation over the rise or fall of a leucocyte count, four and a half precious days on an average, had slipped away, never to return, and the patient comes to the hospital with a gangrenous and perforated appendix and with a beginning or a complete peritonitis.

The following case of general peritonitis is of interest. The autopsy report is typical of these cases:

CASE 8.—A man, aged 24, of poor physique, with indigestion and constipation. During eight months has had several attacks of pain over the appendix, sometimes severe and accompanied with nausea. Two days before admission he was seized with severe pain over the appendix, with nausea and

vomiting. On admission his temperature was slightly subnormal, pulse 108, abdomen as stiff as a board but not distended. Nothing could be determined by palpation. Rectal examination negative. Was very tender over entire abdomen.

Operation revealed a belly full of pus, with an appendix free and not perforated. Appendix removed and glass and gauze drainage introduced.

Patient died 38 hours after operation. Partial postmortem revealed the abdominal cavity full of pus, thick, yellowish and malodorous. Colon and bowel enormously distended and covered with a soft plastic exudate. No perforation of intestine or stomach. Wound in cecum intact. The appendix was 6.75 cm. long, 4 to 6 mm. in diameter, was red, inflamed and swollen. No perforation or concretions. Mucous membrane hemorrhagic in places and slightly ulcerated at tip. Bacteriologic examination of cultures made from abdominal cavity at operation revealed the colon bacillus in pure culture.

Having considered 11, there remain 21 more cases of peritonitis to be discussed. In 19 of these there existed a peri-appendicular abscess of large or small degree and either anterior, posterior or in the pelvis as regards location. Whether the infection of the peritoneum was general at the time of operation or whether the mechanical injury to which the peritoneum was subjected during operation, in the presence of infecting bacteria, was the cause of a resulting diffuse peritonitis, is a matter of conjecture. But at any rate 8 of these 19 cases, shortly after operation, developed the clinical picture of general peritonitis; the belly becoming more and more distended, enema ceasing to be of avail and eserin always proving useless. The bright eye, flushed face, clear mind, rapid, wiry pulse, and the ever-increasing vomiting of a blackish material, partly fecal and partly altered blood, all telling the tale of an, alas, too often recurring story. These patients died on the second to the fifth day, as a rule, and an autopsy would reveal a general purulent peritonitis with many adhesions at the site of operation.

The following case is of interest in this connection, because, while the most conservative treatment was adopted, the patient died.

CASE 10.—A man, 60 years old, without any previous diseases or cause, was suddenly seized with a typical attack of acute appendicitis, promptly developed an abscess and was admitted seven days after onset. He was anemic, temperature 100.4 and a large abscess in the right iliac fossa, exquisitely tender to palpation. Both recti rigid; 19,800 leucocytes.

A few whiffs of ether were given, an incision made into the abscess, its cavity wiped out and gauze drainage introduced. No attempt was made to locate the appendix. The patient died sixty hours after operation. A partial postmortem showed a general purulent peritonitis with gangrene of the appendix and caput coli.

There were six cases which did not develop general peritonitis, and while in these the peritoneum was able by some process, imperfectly understood, to form sufficient adhesions to prevent infection of the general abdomen, yet by reason of its great absorptive power sufficient ptomains and toxins were absorbed to overcome the resistance of the individual. In all of these cases the patients were not admitted until four to six days after the onset and were already septic when operated on.

After operation the temperature ran a septic course, there was a weak pulse, leaky skin, sometimes diarrhea and then hiccough, delirium, paresis of the bowel and a failing heart muscle presaged the end of the patient. Death took place from six to seven days after operation and the autopsies showed an extensive circumscribed purulent or sero-fibrinous peritonitis with damaged kidneys or diseased heart muscle.

The following illustrates this type, with an unusually long course:

CASE 24.—Female, aged 43. Several attacks before the present one. One week before admission was seized with the typical symptoms of appendicitis—pain, tenderness, rigidity and vomiting, with chills and vesical irritability. A mass could be determined on the right side.

Operation revealed a large posterior abscess and with an appendix sloughed off from a necrotic cecum. The abscess cavity was wiped out with gauze, the appendix removed and drainage introduced—glass and gauze into the pelvis, around and in the abscess cavity.

The patient recovered from shock and did nicely until six days after operation when on removing the gauze a fecal fistula began. The wound gradually healed by granulation and there was no untoward symptoms, except a septic temperature and the fistula for four weeks. The patient at this time was sitting up. Thirty-four days after operation she began to have a more decided sepsis, with chills and sweats. Vaginal examination revealed a doughy mass on the right side; but her condition forbade operation and 41 days after operation she died.

Postmortem revealed a localized adhesive peritonitis, a necrotic cecum with a fistula at the appendix site, a secondary abscess of thin brown pus in the median line among the small bowel and a large abscess in the pelvis with a thick wall and containing thick, greenish, malodorous pus. Sigmoid markedly congested.

The median abscess was evidently an infection from the fistula and the collection in the pelvis evidently existed in part at the time of operation and was not taken care of by the drainage.

Intestinal Obstruction.—Whenever many operations for relief of appendicitis are performed, especially in the presence of an abscess, intestinal obstruction must be feared. This condition, which usually does not occur for ten days or more after the primary operation, was met 6 times in this series. In one case the obstruction was not complete and was only discovered at autopsy as a partial obstruction from dense adhesions, the patient dying of sepsis six days after operation. In 4 cases a large peri-appendicular abscess existed with much exudate, and in one of these cases the obstruction did not develop until forty days after operation. The cases cited died from general peritonitis, about the third day after re-operation.

CASE 34.—The sixth was admitted on the second day of an attack of acute appendicitis. Operation revealed a highly inflamed appendix with adhesions to cecum and right iliac fossa. It was ligated and wound closed with catgut tier sutures. The patient developed an ether bronchitis and four days after operation, during a severe spell of coughing, the wound gave way and part of the small bowel was pushed out of the abdomen. Ether was given and the bowel further delivered and washed with saline and then replaced. Cecum was not examined. The wound was closed with through-and-through wormgut sutures with a small gauze drain at the lower end. Four days later symptoms of intestinal obstruction developed, the abdomen was promptly opened and at the ileocecal valve the ileum was found completely obstructed by a mass of adhesions from the free edge of the meso-appendix. These were relieved and the wound closed, using glass drainage and one piece of gauze. Patient died thirty-six hours later.

which lasted a few hours, subsided and remained as a dull ache over the right iliac fossa. Bowels became constipated; vomited at first. On day before admission the pain became more severe. On admission there is rigidity of both recti muscles with tenderness low down in the right iliac fossa; 14,200 leucocytes, 78 per cent. H.B. and 3,740,000 red cells.

Operation under ether revealed a carcinoma about the ileocecal junction, about the size of an orange, very hard and surrounded by dense adhesions. The appendix was tied up in this mass and was acutely inflamed. An ileo-colostomy was performed, using a Murphy button to perfect the anastomosis. The appendix was incised and some escaping pus was wiped away. Gauze drainage was disposed about the appendix and incision partly closed with wormgut. The patient developed general peritonitis and died three days after operation.

Partial postmortem revealed the abdominal cavity full of pus, with anastomosis leaking and ileum at the seat of carcinoma almost totally occluded.

This concludes the deaths from peritonitis, leaving five more to be considered.

Other Causes of Death.—Case 4 suddenly collapsed on the second day after operation from heart failure. Case 22, a man 77 years old with a small abscess about a highly inflamed appendix, died on the third day after operation from pulmonary edema. Cases 5 and 29 died of uremia six and eight days, respectively, after operation. Case 14 was of peculiar interest:

CASE 14.—Miss F., aged 29, always enjoyed good health until one year ago, when she was taken with scarlet fever with a complicating nephritis. Recovered, but has not been in perfect health since, suffering with backache, indigestion and constipation. Three weeks before admission she was seized with severe abdominal pain, most marked in the epigastrium and with nausea, vomiting and constipation. Twelve hours later her bowels were moved and the pain subsided, but has remained as a residual soreness on the right side. On admission there was slight rigidity of the right rectus and tenderness at McBurney's point, etc. Urine showed a trace of albumin only.

Operation revealed an acute interstitial appendicitis with no adhesions. Appendix removed and wound closed with silk tier sutures. Several bleeding points in the superficial fascia had been ligated with catgut.

Recovery was uneventful, stitches removed on the seventh day and on the ninth day patient allowed to sit up, but towards evening was feverish with temperature 101. Wound appeared in good condition.

On the tenth day she suddenly developed a phlebitis of the left femoral vein, temperature 103.2. Wound opened and a small stitch abscess evacuated. But towards evening she began to develop uremic symptoms, with suppression of urine. On the eleventh day the temperature was normal and remained so, but in spite of all efforts the kidneys were inactive and the patient died sixteen days after operation.

The six deaths in children present the following facts of value: All six had a general peritonitis at the time of operation. They were all operated on in the initial attack. The time elapsed between the time of operation and onset varied from two to twelve days. Five had abscesses, three in the pelvis, one post-cecal and one sub-hepatic. In five cases the appendix was perforated and gangrenous. The sixth case had no localized collection of pus, but a general infection of the

DEDUCTIONS FROM THE STATISTICS.—PROPRIETY OF
EARLY SURGICAL INTERFERENCE.

When we consider the awful array of pathologic conditions which appendicitis is capable of causing and that most, if not all, might have been avoided by the early institution of surgical measures, we believe we have sufficient grounds for presenting this paper.

For a disease which has been determined to be a purely surgical malady, we know of no other affection which is as infrequently placed under the direct charge of the surgeon until interference is imperative to save life, as is appendicitis. Why is this so? There are still too many skeptics who do not believe in the propriety of surgical interference prior to the formation of pus. We can not find any reasonable excuse for this state of affairs other than a want of practical knowledge of the living pathology of the affection in question. The time has come when it is the plain duty of all surgeons to insist upon the one sure and safe treatment of appendicitis, early operation. We know of no other surgical measure which is so reasonably sure of success after early operation and when prompt interference means as much to the patient as in acute appendicitis. When the laity cry for early operation it is high time that the medical men be equal to the occasion. Is it not a stigma to our profession to have the laity better versed as to the correct thing to do in this disease than are many of our profession?

By the institution of surgical interference following immediately the onset of the disease the convalescence is curtailed in the majority of instances and the complications and sequelæ prevented. When we compare this with the protracted and uncertain recovery, to say nothing of the complications and sequelæ, the risk to life from acute intestinal obstruction and the awful devastation of the ever-present pus and sepsis in late operations, there is no question as to the choice between the two.

We learn many things in surgery which, as time elapses and our experience ripens, we must forget so as to profit by the work done and seen. There was a time when we firmly believed that an ice bag was an imperative necessity in the treatment of acute appendicitis and that it was wise to wait until the subsidence of the attack, so as to remove the diseased appendix in the period of quiescence. The objection to the use of the ice bag in the treatment of acute appendicitis is like that of opium, but not to the same degree, however, namely, the false sense of security to which it may lead us by partially masking the symptoms; while in certain cases it may do good, still in others it may lose to the patient valuable hours in delay so that perforation may take place, formation of adhesions with or without pus, or the insidious invasion of the general peritoneal cavity follow the onset of the disease, even with the abdomen covered with ice bags. If it is true that by the prompt use of the knife, as our experience shows, our mortality rate is lowered; and further, that the complications and sequelæ are avoided, making more certain the limitations of empirical treatment, then the wisdom of early surgical interference, as opposed to the use of the ice bag and purgatives with the hope that temporary relief will be procured, is clearly defined.

We are satisfied that in years gone by many valuable lives have been sacrificed by waiting for an attack of appendicitis to subside in order to perform the operation of election between attacks. That terrible uncertainty which always exists in appendicitis no longer

should exist, for we are aware that if an attack is permitted to advance to the pus formation stage that we may have any or all of the complications and sequelæ. We are aware that some cases of appendicitis will temporarily improve, but if we follow these long enough there is an entirely different tale unfolded.

To the statement that an amelioration of symptoms in acute appendicitis should always be regarded as favorable and a contra-indication to operation, we take exception. The progressing pathologic process is so uncertain and so difficult, yes, impossible to decipher by the means we possess, exclusive of opening the abdomen, that we clinch this opportunity to operate and thus save lives that otherwise would be lost in waiting for convalescence and the interval stage, which too often does not arrive. We are sure that many will take exception to this, but nevertheless we are forced from our experience to decry such exceptions as false. Even though the symptoms apparently ameliorate, the pathologic process is too frequently hurrying on to the stage of pus formation. To follow this teaching is to practice the rule that proves the best in the majority of instances. To attempt to make ourselves familiar with the pathologic freaks which this disease is capable of displaying is to study the process in the living belly cavity, not in hundreds, but in thousands, and to do this one must be ever present at the side of the operating table; and he who doubts our position we invite to witness our operations at the German Hospital, where we know we can make him a convert to our teaching and practice.

The oft-repeated, old, old story of procrastination is nowhere better illustrated than in connection with the delay in waiting for the interval operation. There is a temporary improvement under the application of the ice bag and administration of laxatives, which, however, should not mislead anyone, as it often is immediately followed by an exacerbation of the symptoms of the disease, indicating a perforation of the appendix, or the formation of pus or its dissemination. Even while the apparent lull in the appendiceal storm is on, grave complications are making headway in the abdomen, out of sight and out of reach of the examining finger. We all of us know that the temperature and pulse rate are of no diagnostic value in many instances and that the dangerous constitutional evidences of the disease are not made manifest until the irreparable damage has been done and too often a dear and valuable life sacrificed.

The appearance of shock or collapse early or at the time of onset of a secondary attack means but one thing, perforation of the appendix has taken place. We are convinced that all the fulminating cases of appendicitis are such because they almost always occur in a secondary attack of the disease. How often has it been the experience of a surgeon to hear the statement made that the collapse came as a thunder-bolt out of a clear sky, and after a careful inquiry into the previous history of the case, find that the patient has been the subject of many premonitory symptoms of appendiceal irritation with the culmination of this disastrous state of affairs.

It is on account of the many, many accidents complicating the disease during an attack and because so many fatalities attend subsequent attacks that we have determined to disprove of the interval operation and come out flat-footed against delay in the primary attack.

Acute intestinal obstruction following delayed operation in acute appendiceal disease has occurred most frequently in our experience in the right iliac fossa and made its appearance after ten days or two weeks

had elapsed and in a most insidious way. While recognized promptly and an operation instituted for its relief directly after its recognition, the results have not been at all reassuring. It has been our practice where obstruction is suspected to open the abdomen on the appearance of paroxysmal pain with nausea or vomiting and inability to move the bowels or pass flatus.

A glance at the table of statistics shows that the mortality of the operation for the relief of obstruction is 60 per cent. Now, our friends who decry early operation can not say that this sequel to the delayed operation for appendicitis is a point in favor of delay. It is a fearful commentary on the obstinacy of some, who, in defiance of the many discussions which this disease has undergone and the gradual conversion of many to the conclusion that there is something in the surgical treatment of appendicitis after all. These same fanatics continue to raise a hue and cry, both by voice and in print, against the too frequent use and abuse of the knife. There is no doubt in our minds that had early surgical interference been instituted in the cases which subsequently had obstruction, before the adhesions formed, they would still have been alive and well.

SECONDARY ABSCESESSES.

Secondary abscesses, a result of acute appendicitis, occur frequently enough to warrant a few passing remarks on their origin, significance and their prevention. The convalescence of an appendix case complicated by abscess is in many instances uncomplicated, but unfortunately in others a secondary collection forms which may seriously jeopardize the patient's recovery or prolong the convalescence to such an extent that an undermining of the constitution results, which leaves the sufferer an invalid for a long period of time and in some instances is followed by a neurasthenic state from which they never entirely recover, or, as instanced in this paper, result in death from a collection at a point far distant within the peritoneal cavity.

The evacuation of the primary focus of infection does not necessarily mean the removal of pus from a secondary abscess. A secondary collection is often exposed upon breaking up the adhesions which help to form the wall of an abscess cavity, and it is our practice to do this in certain cases, not only in the hope of finding a secondary collection, but to avoid contraction of the abscess wall and in this wise prevent an intestinal obstruction. It has been a safe practice in the author's hands to break up the adhesions forming a portion of the abscess wall, provided that the proper use of gauze has been made to safeguard the general peritoneal cavity.

FECAL FISTULÆ.

Fecal fistula, a distressing and preventable sequel to appendicitis, occurs always as a result of progressive and destructive inflammatory action consequent upon a late operation for the disease, and is due to one or two causes, a softening of the surrounding bowel wall from micro-organismal invasion, or to the subsequent breaking down of the bowel from interference with its nutrition, also due to the acute inflammatory disease. A fatal termination occurs in a certain percentage of non-operated fecal fistulæ. The involvement of both the large and small bowel in a fecal fistula leaves the patient in a very precarious and dangerous condition, owing to the interference with the nutrition and the escape of the very elements of nutrition through the fistula.

Any operation for the repair of a fecal fistula, no matter when performed, is attended by danger and risk to life. There are a few instances where the fecal fistula closes spontaneously. Our experience with fecal fistulæ closing spontaneously has not been so happy as many of our colleagues, judging from their reported cases. We have occasion to repair many cases of fistulæ, not only in our own patients but those of others, where as long a time as one year has elapsed without spontaneous healing having taken place. In a percentage of these cases the lesion has been more than a fistula, an artificial anus. It is not our practice to interfere in the case of a fistula, unless it be of the small bowel and attended by the escape of the essential nutrient material, until a considerable time has elapsed and healing not taken place.

COMPLICATIONS.

The complicated cases of appendicitis present so many phenomena that the merest mention only of the more prominent can be made, owing to the limited time permitted to the subject. Among the more common complications are: General peritonitis, involvement of the omentum with abscess, abscess of the mesentery, and inflammation of the lymphatics of the mesentery glands followed by abscess, abscess between the coils of small bowel, pyemia of the portal system the result of phlebitis of the veins of the meso-appendix, with or without metastatic liver abscess, gangrene of the cecum, colon and small bowel, abscess of the liver from contiguity of structure, septic nephritis, septic meningitis and phlebitis of the lower extremity, particularly the left, but sometimes both.

Phlebitis as a complication of appendicitis never occurs except as a result of infection; when phlebitis is a sequel to chronic appendicitis operations there will be found some point of oversight in the technic that accounts for the infection. Phlebitis may be a serious complication and may cost the patient not only their future usefulness, but may also have a fatal termination, as instanced by embolic obstruction.

OTHER SEQUELÆ.

The three sequelæ of acute appendicitis most commonly met are fecal fistula, hernia and intestinal obstruction.

Hernia as a sequel to acute suppurative appendicitis in our judgment always follows the extensive use of drainage and, we are almost prepared to say, in all instances where drainage is used. Like fecal fistula, it is preventable and the operation for the repair of the defect in the abdominal incision is attended by a much greater risk than is the primary operation, if done at the opportune time. A successful result is not always obtained for several reasons: first, because the tissues are so thinned out that any attempt at repair is followed by a recurrence of the hernia and, second, the possibility of an infection of the wound or of the peritoneal cavity, thereby causing the patient to assume the risk of peritonitis twice where it should not have been a possibility in the first instance.

The painful dressings occasioned by the removal of the protective gauze packing and drainage and its reinsertion in suppurative cases play an important rôle in the convalescence; not only does it cause the patient great pain and anxiety, but it may be a possible source of contamination to the peritoneal cavity, if through any mischance in the effort to repack the wound protecting adhesions are broken through. We believe that these dressings are, in a percentage of cases, the cause of an undermining of the nervous system.

APPENDICECTOMY.

The appendix should be removed in all cases where operation is done early. In late cases whether the appendix should be removed must depend upon the skill and experience of the operator, the local condition and the condition of the patient. We have in a few instances, as will be noted in the foregoing pages, refrained from removing the appendix, contenting ourselves with simple evacuation of the abscess. The patient's condition was so shockingly bad that we did not consider it wise to do more than evacuate the abscess. A patient whose condition is so bad that operation on the abscess cavity is alone warranted is not in any way promising. The mere evacuation of an appendiceal abscess without the removal of the appendix does not cure appendicitis, and any surgeon who so informs his patient practices a deception; while it may possibly be done without the intent to deceive, it is a fact nevertheless. Occasionally the operator is led to believe that the appendix has sloughed off because a mass of lymph floats out of an abscess cavity. We have, on more than one occasion in the distant past, been led to suppose that this was so, but a riper experience has taught us differently. A careful survey of the abscess wall under these circumstances has found the appendix imbedded in lymph, although completely severed from the cecum. When in the evacuation of an appendiceal abscess a mass of lymph shaped like the appendix is seen in the abscess or to float out with the pus, it must not be supposed that this is the appendix. We admit that this may look not unlike the appendix, yet a careful examination to settle the question is in order. To entertain the thought that the evacuation of the appendiceal abscess spontaneously by way of the bowel, pelvis or the ureter, bladder, through a bronchus or any other internal avenue, or externally, even by the knife, is a safeguard against subsequent attacks of the disease is not borne out by the experience of those of us who operate upon cases presenting such a history or who operate for the cure of hernia or a fistula following these evacuations. Under these circumstances we have operated many times, and have yet to find the appendix absent. Some of the largest appendices we have removed have been in cases of this character.

LEUCOCYTOSIS.

A word about the white blood count in acute appendicitis. In our experience a leucocytosis is present in the majority of cases. That it is of any particular moment in only the doubtful cases we are convinced. In any but doubtful cases, and these are few, for the diagnosis of this ailment, particularly if seen early, is not a hard one to make. To defer operation for any length of time until a blood count is made is to expose the patient to a risk not justifiable and places the medical attendant, be he physician or surgeon, in a position which makes him censurable. To take out an healthy appendix, if there is such a thing in a believed case of acute appendicitis, is much less a crime than to jeopardize a patient's life by deferring operation in a bona fide case until a leucocytosis is present. A leucocytosis in gangrenous appendicitis is not often present, owing to the lowered resistance of the patient; therefore if depended upon under these circumstances what may be the patient's only chance to get well, operation, has been deprived him.

Leucocytosis in late cases, where that often referred to and by many hoped for condition, walled off abscess, is present, is frequently absent. Microscopic doctors are

of value if confined to the laboratories, but in the sick room they are useless.

CONCLUSIONS.

In concluding this abstract we will summarize the lessons learned from the preceding facts. Early operation means cure. There is no doubt as to obtaining a good result if the case be operated on while it is still one of appendiceal colic and not deferred until acute inflammation of the appendix has supervened. Deferred operation means protracted convalescence and invalidism or death. It is better to take out an occasional healthy appendix than to leave one that may cost a life.

APPENDICITIS.

A BRIEF REPORT OF THE AUTHOR'S NINE FATAL CASES, WITH COMMENTS.*

PARKER SYMS, M.D.

NEW YORK CITY.

THE CASES BRIEFLY NARRATED.

CASE 1.—Mr. L. July, 1891. Age over 60. Perforated appendix; incomplete adhesions; slowly progressive, general peritonitis; general sepsis; typhoid condition at time of operation.

Operation.—Tenth day. Lateral incision; appendicectomy; general peritoneal irrigation; iodoform gauze, packing and drainage.

Peritonitis and sepsis progressed and patient died a few days after the operation.

CASE 2.—V. L. October, 1895. Age over 60. Fulminating gangrenous appendicitis; no adhesions; general acute peritonitis and peritoneal sepsis.

Operation.—At thirty-sixth hour. Free incision; appendicectomy; irrigation; iodoform gauze packing and drainage.

Continued sepsis. Death thirty-six hours after operation.

CASE 3.—W. S. Age 6 years. Fulminating type, gangrenous appendicitis, with perforation; very large concretions; no adhesions; acute general peritonitis; peritoneal sepsis.

Operation.—At twenty-fourth hour. Free incision; appendicectomy; irrigation; gauze packing and drainage.

Death within thirty hours.

CASE 4.—Mr. C. August, 1898. Age 20 years. Fulminating type of acute gangrenous appendicitis with large cast-like concretions; general peritoneal sepsis.

Operation.—Thirtieth hour. Free incision; appendicectomy; peroxid irrigation; dry sponging; gauze drainage.

Death within twenty-four hours.

CASE 5.—L. E. B., Feb. 4, 1899. Age 11 years. Acute perforating appendicitis; abscess behind cecum and free pus in abdominal cavity; extensive progressing peritonitis. Patient was brought to the hospital from a distance of seven miles sitting in a buggy.

Operation.—Fifth day. Free incision; irrigation; hydrogen peroxid; gauze packing.

Peritonitis and sepsis continued to progress. Death on the fourteenth day.

CASE 6.—J. G. May 24, 1899. Age 37 years. Gangrenous appendicitis; gangrene cecum; perforation without adhesions; general suppurative peritonitis. Patient brought to hospital on fifth day, the appendix having ruptured before his admission.

Operation.—Free incision; appendicectomy; peroxid irrigation; dry sponging; gauze drainage. Abdomen was found filled with foul-smelling pus.

General peritonitis and sepsis. Patient died within thirty hours.

CASE 7.—Wm. M., Jan. 30, 1900. Age 37 years. Gangrenous appendicitis; general suppurative peritonitis; peritoneal sepsis. Patient was admitted to hospital on the third day of attack.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard.

Operation.—Third day. Free incision; gangrenous appendix removed; peroxid irrigation; gauze drainage.

Sepsis continued. Death within thirty hours.

CASE 8.—Mr. C. October, 1900. Age 26 years. Acute suppurative appendicitis; perforation on the third day without adhesion; general suppurative appendicitis.

Operation.—Some hours after perforation; free incision; appendicectomy; peroxid irrigation; dry sponging; gauze packing.

Peritonitis and sepsis continued. Patient died on the second day after operation.

CASE 9.—Miss D., Oct. 25, 1901. Age 14 years. Acute suppurative appendicitis; localized peritonitis; perforation into adhesions. Patient was not seen until late.

Operation.—On the sixth day. Free incision; evacuation of abscess; peroxid disinfection; gauze drainage.

At time of operation the patient was in a very weak condition. A rather prolonged search through the adhesion for the appendix did not disclose it and as it seemed wise to terminate the operation on account of the patient's condition, the appendix was not removed, but the abscess drained. Patient apparently did well for about ten days; the temperature became practically normal, the wound was rapidly healing, and the author turned the case over to the family physician for final treatment, when the patient went into sudden collapse with symptoms of perforation and died within a few hours.

COMMENTS ON THE CASES.

By reviewing the above cases it will be seen that five of them, namely, Nos. 2, 3, 4, 6 and 7, were of the type of acute gangrenous appendicitis, rupturing into the peritoneal cavity without adhesions. Three of the cases, namely, 1, 5 and 8, were of the type of perforating, suppurative appendicitis without adhesion or with incomplete adhesions in which there was free pus in the peritoneal cavity, with acute general peritonitis, or with progressive suppurative peritonitis. In only one case, namely No. 9, was there a circumscribed abscess. In fact, this latter case is the only one in which a fatal termination was not expected and predicted.

On carefully inquiring into the histories of these cases it was found that nearly all of them had had previous attacks from which they had apparently recovered, or that they had had symptoms to which they had paid but slight attention, but which would easily have been recognized by a skilled diagnostician; and had they been operated on at one of their earlier attacks, or at any time previous to the final breakdown of the appendix, it is fair to assume that they would have recovered.

IMPORTANCE OF EARLY OPERATION.

It is a conviction of the author that death from appendicitis is due to but one thing; that is, too late an operation. In every case of fatal appendicitis there has been a period when the patient could have been operated on successfully and safely.

One of the points which the author wishes to make is that appendicitis is purely a surgical disease and that it can only be treated properly by surgical intervention. Time would not permit, nor would it be fitting here, to set forth arguments in support of this statement, but it is a statement which can be fully sustained by sound reason and by good practice.

Some years ago the author set forth his views concerning the proper method of treating appendicitis, and with very little alteration that method serves him today. It embraces, first, the palliative treatment; second, rules for operating on an interval case; third, rules for operating on an acute case with circumscribed peritonitis with or without abscess; and fourth, rules for operating on an acute case with general peritonitis.

PALLIATIVE TREATMENT.

According to present knowledge palliative treatment is properly applicable to a very limited number of cases, namely, only those in which there is some strong contra-indications to operation, or in those cases in which an experienced surgeon will feel comparatively sure that the patient is proceeding to prompt recovery and in which he may look forward to safe postponement of the operation to the time of the interval. The treatment is very simple and is as follows:

Put the patient in bed and keep him there.

Apply over the whole of the right iliac region a soap "poultice," consisting of green soap spread on a single layer of muslin or linen.

Over this apply a broad ice bag or an ice coil.

Relieve the bowels daily by soap and water enemata.

Keep the stomach at rest while vomiting exists.

Restrict the patient to milk, if he can take it; if not, give him clear broth, never solid food.

Note the temperature, pulse and respiration every four hours.

Have all preparations made for an immediate operation.

Remember that your treatment is purely expectant.

Give no drugs.

Never give opium or morphin in cases of appendicitis except in case of abdominal shock from rupture of appendix or of abscess.

OPERATIVE TREATMENT.

There are certain general rules that the author applies to all forms of operations. These will be touched on at once, and then will be taken up the special indications and procedures.

He insists on having one of his own assistants when possible, considering that the protection of the peritoneum by gauze packing and the retraction of the wound are of the utmost importance. It is also important to have a nurse who is thoroughly familiar with the operative methods. The entire abdominal surface should be sterilized as completely as possible. There should be prepared a proper operating table. The Trendelenburg posture should not be employed. Hand sponges and flat laparotomy sponges should be made of sterilized gauze arranged in packs of ten and carefully counted and recounted after the operation. For catching and removing pus on opening an abscess small marine sponges are used on holders. The patient should be slowly and carefully anesthetized. When thoroughly narcotized and the muscles relaxed, a final examination should be made. The operation should be done deliberately and carefully, but with all compatible speed.

We now come to rules for the special form of operation.

(a) *Rules for Relapsing and Recurrent Appendicitis—Interval Operation.*—After the patient has been thoroughly anesthetized, the skin properly prepared, the operation field thoroughly surrounded and protected by sterilized coverings, the operation is done as follows:

An incision is made external to the border of the rectus, parallel to the fibers of the external oblique. Its middle point should be on a line drawn from the umbilicus to the anterior superior spine of the ilium. The external oblique fibers should be separated without cutting and the internal oblique may be opened by cutting or splitting, according to the preference of the operator. The transversalis is opened in the same

manner. When the peritoneum is reached it should be lifted between two mouse-toothed forceps and divided, such care being taken as to positively insure against wounding the intestine, whether there be any adhesion or not. Of course, before opening the peritoneum all bleeding should be arrested.

When the peritoneum has been sufficiently opened the index finger is introduced and the region of the appendix explored. If adhesions are found, the entire wound should at once be enlarged so that the necessary separating and dissection may be done with facility and in plain view.

If there are no adhesions the wound may be a very short one in a very thin subject, not exceeding one inch in length, but it always should be large enough to enable the operator to do his work properly. When the appendix is found, if it is free from adhesion, its tip should be brought out of the wound and the mesentery should be divided between fine catgut ligatures. When the appendix is separated from the intestine, except at its base, it and a portion of the intestine should be brought out of the wound, so that the ablation can be done extraperitoneally. The author passes the appendix through a hole in the center of a flat gauze sponge, which gives excellent protection to the peritoneum.

The author passes a Lembert suture at each side of the base of the appendix and one at its middle, leaving the loop long; the first two are used as retractors holding up the intestine. The appendix is now cut off about half an inch from its base. Its canal is probed to be sure that it is pervious, then with a fine forceps the stump of the appendix is invaginated and the middle Lembert suture is tied as the forceps are removed; then the other two sutures are tied and the orifice is thus completely closed by Lembert sutures. The immediate region is disinfected with a drop of peroxid of hydrogen, the intestine is returned to the abdomen, the abdominal wall is closed with one through-and-through suture of catgut if the incision was short, more being used if necessary. A collodion dressing is applied. This operation is done as an aseptic procedure. It will require from 15 to 25 minutes to perform.

The after-treatment is very simple, consisting of rest in bed for one week, fluid diet for four days, enemata daily. The patient should be fully restored to health and his usual occupation anywhere from the eighth to the fourteenth day.

(b) *Operation for Acute, Suppurative or Gangrenous Appendicitis with Localized Peritonitis, with or without Abscess.*—After the preparation of the patient and operation field above described, a similar incision is made, but it must be extended at either end and should be at least four inches in length. The external oblique is opened by blunt dissection; the rest of the layers should be clean cut, and care should be taken not to separate one layer of the wall from another. If the aponeurosis and fascia are stripped bare they are very apt to slough, and thus leave a very weak wall.

The essential part of this operation consists of the intraperitoneal work in searching for and treating the abscess, if one exist, and in searching for and dealing with the appendix. The most important thing of all is the protection of the uninvaded peritoneum. This requires the exercise of sound judgment to determine how much to do, and of knowledge and skill to do it properly.

As soon as the peritoneum is opened sponge packing should be begun. Throughout the operation this must

be done in such a manner that no infected tissue nor disease product can come in contact with healthy peritoneum. The first assistant must take entire charge of this.

When all the open spaces around the mass of adhesions have been completely closed by dry gauze pads, the wound should be well retracted and the tumor gently entered by separating adhesions and by blunt dissection. When an abscess is reached the author makes a pin-hole opening, and at once prevents the escape of pus by pressure of a small sponge held in an artery clamp. After a minute the sponge is replaced by a clean one and the pus is removed drop by drop, all of it being absorbed by these sponges and none of it allowed to escape into the wound. After pressure is sufficiently reduced by emptying the abscess the opening is gradually enlarged, and finally the cavity can be thoroughly sponged out. Now it should be freely opened and its interior disinfected with hydrogen peroxid. The size of the abscess will depend on the duration of the disease. Its walls are composed of adherent intestines thickly coated with plastic lymph, and the ruptured or perforated appendix usually forms some part of this wall.

We have now reached the point when the average of the results will depend on the judgment of the operator. If he is wise he will remove the appendix in only those cases in which it can be readily found and removed without separating too many adhesions. If he is rash, he will unduly persist in his manipulations, and in many cases he will break through Nature's safeguard at some point unseen and cause the death of his patient by secondary infection.

If the appendix can with safety be removed, it should be separated from the intestine with great care and gentleness, its mesentery properly ligated; then it should be ablated about a quarter of an inch from its base, and the canal thoroughly sterilized with the cautery. Now a single ligature of catgut should be tied around the appendix, including all its coats, then the superfluous stump beyond this ligature trimmed away with the cautery or scissors. Now the operator should thoroughly resterilize his hands, and all towels, etc., about the wound should be replaced by clean ones.

One or two sutures may be used at each end of the wound, but an ample opening must be left, for the wound must be treated by packing. Remember that in packing a wound for drainage you must not proceed as you would if you were calking a ship to prevent leakage. These wounds, whether the appendix has been removed or not, should be packed as follows: One piece of iodoform gauze, folded longitudinally, is passed to the bottom of the abscess cavity and brought out of the wound, and turned to the outer side of the wound. It should be large enough to completely fill the cavity, but not to stuff it. Now, as the first assistant slowly removes his gauze pads they should be replaced by pads of iodoform gauze which must be carefully protected from any contamination. These pads must completely close any spaces where adhesions are wanting, and they must come in contact with healthy peritoneum and separate it from all infected areas. Careful note must be kept of the number of pieces used.

Now the entire wound should be covered by first a pad of iodoform and then by several pads of plain, sterilized gauze; flat ones are the best. These should be firmly held by strips of adhesive plaster. Over this a thick layer of absorbent cotton is placed and secured by an abdominal binder.

In case the operation is done before the appendix has broken down, and there is no circum-appendicular abscess, the procedure should be the same as the one just described; but the appendix can be removed in nearly all instances.

The after-treatment of these cases is most important. It should be as follows: Complete rest of the stomach for twelve hours. Peptonized milk in small quantity after twelve hours, if there is no nausea or vomiting. Patient should be kept quiet on his back for four days. Enema of soap and water every day; if there is much tympanites, turpentine should be added.

The outside dressing should be removed at the end of twenty-four hours, and changed as often after that as it becomes saturated. The packing should not be removed until the fifth day—that is, on the fourth day after operation. This needs to be done as carefully as the operation itself. Retractors should be used and the wound well opened. Then the gauze should be removed from the tumor cavity. This should be thoroughly cleaned by dry sponging. No fluids should be used. Now this cavity should be carefully repacked, and then the protecting pads should be gently separated from the adhesions they have caused and new pieces substituted.

After this the wound should be dressed every third day. Soon a single packing will be sufficient, and this should be reduced in size at each dressing. The patient should be kept on fluid diet for one or two weeks, and be kept in bed until the wound is healed to a narrow sinus, which it will be in from three to five weeks. When the patient gets up he should wear an elastic binder for one year to prevent hernia.

No drug treatment will be needed. The author insists on his rule concerning morphin. These patients will be comfortable and free from pain if they have not been reinfected at the operation, unless the case were already one of progressing peritonitis.

(c) *Operation for Fulminating Appendicitis, with Rupture or Perforation of Appendix, with General Peritoneal Involvement.*—This operation must accomplish removal of the appendix and of all infective material and the cleansing toilet of the entire peritoneum. When the diagnosis of this condition is positive, a large median incision should be made. The right iliac region should first receive attention. If the appendix is still attached, it should be removed and the stump secured. If the appendix has sloughed off, the intestinal orifice must be closed. With one hand in the abdomen, a separate opening in this region should be made for special drainage.

Now every portion of the visceral and parietal peritoneum must be cleansed by thorough sponging, which shall remove all inflammatory products and all foreign material. After this is done, every portion of the peritoneal surface must be washed again and again with hot salt solution (6 to 1,000). If the patient's strength will permit it, the intestines should be systematically, coil by coil, washed outside of the abdomen. The work should be done thoroughly; but it must be done rapidly, for these patients are always in a bad condition. Often you will be obliged to be incomplete in your work to avoid death on the table.

After the cleansing is accomplished, gauze packing should be used so as to drain the entire abdominal cavity. Enough suturing should be done to prevent escape of the intestines into the dressings. A very large dressing must be applied externally; this should be changed in a few hours.

In these cases opium is called for to relieve the pain and as a stimulant against shock. A full dose should be given before operation.

The foregoing rules for operation were adopted by the author years ago, and he has had no reason to modify them materially. While he now removes the appendix in nearly every case, he still feels that there are cases in which it is safer to resist from such attempt than to persist.

In support of the reasons which have led the author to continue to put in practice the principles here set forth, is the fact that in thirteen years of operative work in this field, while he has lost nine patients, but one of those has been of a type of disease which is considered amenable to treatment.

50 West 47th Street.

ANOMALIES OF APPENDICITIS.*

ERNEST LAPLACE, M.D.

PHILADELPHIA.

Although the question of diagnosis of appendicitis is treated as an easy matter by the majority of writers, it still remains of extreme difficulty, owing to the varying data of a given case. Appendicitis is not a self-limited disease, presenting a typical course; it is an anomalous disease.

The following points, gathered by the writer from notes in his own work, point to the extreme care which a case may demand in its diagnosis and subsequent management.

LOCATION OF APPENDIX.

The appendix is not always located in the right iliac region. Twice it was found adherent to the liver; once to the gall-bladder; twice to the urinary bladder. In very stout patients a certain degree of enteroptosis is present and changes materially the location of the appendix. One may then expect to find it in any part of the abdominal cavity, according to the particular location in which the ileocecal region accommodates itself. Under these circumstances the location of pain becomes a very obscure matter. It may be found at any portion of the abdomen, radiating in various directions. Again, the location of pain is the result of educated sense; hence, the accuracy with which it is located about the tongue, fingers and surface of the body, generally. Not so, however, with the parietal peritoneum, which, untrained to sensation, is not prepared to refer pain to the exact spot of irritation. These two elements join to make pain and its location an uncertain factor in the absolute diagnosis of appendicitis.

VARIETIES OF MICRO-ORGANISMS.

It is generally conceded that infection is the cause of appendicitis. Sometimes this infection is secondary to the irritating presence of a foreign body. But the infection itself is not uniform and presents numerous anomalies which depart from a typical infection. The multitudinous and varying clinical aspects of cases arouse in us the search for a cause to account for each clinical picture. In vain do we search for such a cause. We know that a foreign body or enterolith alone and sterile would become encapsulated and produce no inflammatory result. Infection is, therefore, the true cause.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard.

Bacteriologic examination reveals but three or four organisms—the bacillus coli, the staphylococcus, the lanceolatus, the streptococcus, and still the wonderful variety of lesions found about the appendix throughout its histologic structure, as well as the uncertain clinical appearances of the affection, would demand many more contributing etiologic causes. It behooves us, therefore, to examine into the bacteriologic element in the course of an attack of appendicitis. When Pasteur discovered the cause of anthrax and found that the *bacillus anthracis* caused death in animals whose temperature ranged from 98° to 100°, he also discovered that this same organism, when cultivated at 103 F., had lost so much of its virulence as now to serve as a vaccine for the cure of animals afflicted with the growth of this germ at their normal temperature. In other words, he established the fact that, organisms vary constantly in their virulence, and can be made to rise and fall in their irritating and poisonous effect, according to the nature of their surroundings.

Temperature, light, moisture, the nature of the soil and especially the degree of restricted space and soil to which their growth is limited: these principles are the ones from which we should seek the explanation of the various features of appendicitis.

THE VARIATIONS IN SYMPTOMS DUE TO DIFFERENT MICRO-ORGANISMS.

We will consider: 1, The varying virulence of the bacteria and their toxins during the course of an attack; 2, the reaction of these on the tissues, producing the histologic changes that extend from the fulminating gangrenous form, which is expressive of the most violent and acute inflammation, to the so-called appendicitis obliterans, expressive of the mildest type of irritation and producing a chronic inflammation.

Like the colon, the appendix has a serous, a muscular coat consisting of transverse and longitudinal fibers, and a mucous membrane, which has tubular glands and lymphoid tissue. At its opening into the cecum is a fold of mucous membrane—the Gerlach valve. The movements of the appendix are partly restricted by its meso-appendix, which does not always extend to its tip, and as a result may cause the appendix to curl upon itself during its vermicular movements. The histology of the appendix shows that, like all functionless organs, leading a retrograding existence, its self-protecting properties from circulation and phagocytosis are also restricted. With these premises we assume:

1. That all the bacteria found in the diseased appendix are also found in the healthy appendix and colon.

2. That a higher degree of virulence is the only cause whereby these organisms now irritate.

What, therefore, are the causes of the increased virulence of the bacillus coli and streptococcus? We know that an acute diarrhea or enteritis gives symptoms quite comparable to appendicitis, only more widespread. The bowel soon rids itself of the irritating fluid material, germs and all. But in the appendix drainage may not be possible, and from that time trouble begins. The micro-organisms which irritate the appendix as they do the gut, produce a swelling of the mucous membrane of the appendix, which tends toward occluding its lumen at any spot along its course, but more especially at its base, where is located the fold of mucous membrane known as the valve of Gerlach. It is then that the retained germs, growing in a limited area, rise in virulence, gradually, and at times produce a toxin so violent as to cause the same destructive changes on the substance of the appendix as would be produced

by so much nitric or sulphuric acid, causing gangrene of the organ in mass. The streptococcus is chiefly responsible for this type. We know that if it is confined in its development, gangrene of the foulest type results, as took place in pre-antiseptic days when pus often remained several days in a wound, producing hospital gangrene, now so seldom seen, owing to antiseptics and drainage. We all know the rapid and violent clinical course of this type and parenchymatous gangrene of the accompanying appendix, pain and rigidity of the right iliac region (sometimes of the whole abdomen), high temperature and a rapid bounding pulse.

When the bacillus coli infects, the case starts with quieter symptoms; there is generally a retention of fecal matter, and on the absorption of most of the liquid portion a fecal concretion or enterolith results, glued with mucus, and containing many exfoliated epithelial cells of the diseased mucous membrane of the appendix. In every case where the writer has found a fecal concretion the case presented also a history of one or more previous attacks of similar nature as the present one. In other words, hard fecal concretions are the result of a long-continued retention of feces in the appendix, antedating the present attack. Here, according to the virulence of the toxin generated by the organisms, within and around the fecal concretion, will the case result in a local gangrene surrounding the area of the concretion, or else the toxins being of a milder character, simply keep up chronic irritation of the appendix, resulting in adhesions of the appendix in various positions, and also excite a perityphlitis causing adhesions of the colon to neighboring structures. It is this type that results in the so-called obliterating form of appendicitis, which simply means that the irritation, constant but never very violent, has succeeded in destroying the mucous coat at the bottom of the appendix, caused granulations to form and an adhesion of the sides from the bottom up takes place by granulation, exactly after the cicatrizing manner of a wound which we force to heal from the bottom by packing. In this instance extra-appendiceal abscesses may also occur, either at the base bounded by the ileum, colon and omentum, or even at a distance in various positions of the abdomen. Here comes a most important complication which so often veils the clinical signs to be expected from such an infection as has just been described, that is, the presence of a mixed infection. The streptococcus may suddenly appear and give to the chronic type an acute exacerbation. The temperature, heretofore ranging between normal and 100° F., may take a much higher course with a corresponding modification of the pulse. The saprogenic germs may by their toxins further cloud the course of the original infection.

THE ABORTIVE TREATMENT FOR APPENDICITIS.

When chronic adhesions have existed and the spot then becomes one of least resistance, it also becomes a favorite soil for the development of the tubercle bacillus, hence the type of chronic abscess, much like the ordinary cold abscess which may be found in connection with a diseased appendix. Sometimes the appendix has entirely disappeared or disintegrated in the tuberculous process, and nothing but the so-called pyogenic membrane, tough and unyielding, is present, the colon and ileum in that region being also masked by it. Finally, cases may present a combination of these various types to such a degree that it is perfectly safe to state the following as an axiom: At no time during any attack of appendicitis is any one sure of the extent

perforative appendicitis the fourth day after the attack began. He had received on the day he entered the hospital, every hour, half an ounce of salts, which was the cause of his death. No operation was performed, as he was dying when admitted.

CASE 6.—This case might possibly have been saved by an operation. He was a very emaciated sickly child, 8 years old, suffering from perforative appendicitis for one week before entering the hospital. He had a mild form of diffuse peritonitis, and if his abdomen had been drained at once he might possibly have been saved. His condition was so low when he was admitted that it seemed to me he would have a better chance without than with an operation, but it is possible that my judgment was wrong in this case.

CASE 7.—A child, aged 4, was in a dying condition when admitted. No operation was performed.

CASE 8.—A child, aged 4, had received food and cathartics the day before coming to the hospital. It seemed to me when he entered the hospital that he was still on the safe side. I consequently operated at once. I thought an operation would relieve him, but he died from diffuse peritonitis. This case might have been saved by waiting.

CASE 9.—This case was one of diffuse peritonitis at the age of 44. He came to the hospital at the end of an acute attack, suffering from a circumscribed abscess. I made an incision at once and did an extensive operation, loosening many adhesions. He died of exhaustion after two weeks. I believe he would have lived if I had simply drained the abscess and had not removed the appendix from its deep location. The operation was too extensive in his weakened condition.

CASE 10.—This case was one of extensive diffuse peritonitis in a woman 32 years of age, who entered the hospital on the fourth day of her attack extremely ill. She was placed on exclusive rectal feeding. Gastric lavage was performed. She improved so that she could take liquids after three weeks. At the end of the fourth week I operated, removing a perforated appendix in a circumscribed abscess. All the intra-abdominal organs were diffusely adherent, so far as I could explore. Death resulted from pneumonia on the seventh day after the operation. The abdominal wound was normal.

Of these cases I believe the 2 that died in the interval should have lived. I think 2 cases at least, and probably 4, of the other 10 could have been saved. Five of the 10 patients who died were not operated on, and these are the only cases in the entire number of 416 which were not operated on. Four of these cases were admitted in a dying condition and would not have been operated on by any one, and should consequently be excluded from the list, but this would leave the statistics open to the criticism that there might be a difference of opinion regarding the moribund condition. Case 6, although not operated on, should be charged to the method, although his weakened condition (he had been an invalid from infancy, being a rachitic child) practically precluded the possibility of a recovery.

During the same time I treated a number of cases of acute perforative appendicitis by this method who recovered but have not been operated on. These I have not included in this list because the diagnosis has not been confirmed anatomically. But there can be no reasonable doubt about the correctness in the diagnosis in these cases, and if counted they would still further reduce the percentage of mortality.

I will state, also, that all of the ten cases of acute perforative appendicitis which died had been previously treated by the use of cathartics and food by mouth, and that of all the cases which received neither food nor cathartics from the beginning of the attack there has been no death.

The fact remains that there is a distinct class of appendicitis cases in which the mortality after an immediate operation is especially high in which the vast majority of the patients may be saved if they receive absolutely no food nor cathartics by the mouth, the operation being postponed until it seems safe. A slight amount of rectal feeding, consisting of one ounce of one of the liquid concentrated foods in the market dissolved in three ounces of warm normal salt solution given by the rectum every four hours is sufficient. Small sips of hot water often repeated are usually borne well.

DR. J. D. SULLIVAN, Brooklyn—From this discussion it seems to be the general consensus of opinion that early operation is the proper treatment for every well-defined case of appendicitis. It appears to me that our knowledge of the disease makes it our duty to advise and practice early operative treatment as the only safe course to pursue. It is a great advantage to the patient to be able to close the wound and obtain primary union. This is one point I wish to make in favor of early operation. The sooner we operate after recognizing the disease, the better are our prospects for closure of the abdominal incision and primary union. The advantages to the patient and surgeon of closing the abdominal wound are so many and so great that I now practice this method in cases where I would formerly employ drainage; and with better results. If there has been some local peritonitis without the formation of an abscess, or even if there has been a moderate degree of general infection without the formation of pus, I usually wash out the abdominal cavity with a large quantity of saline solution, employing for this purpose a long glass tube attached to a fountain syringe such as is used for washing out the uterus, and having the water at a temperature of about 110 F. I insert the tube through the wound down into the pelvis, and while the water is flowing I move the tube about to the most distant parts of the abdomen so that the flushing is from the tube toward the opening in the abdominal wall. Having made use of three or four gallons of warm saline solution in this way I deem the abdomen sufficiently clean to warrant a complete closure of the incision. If I think the surface of the wound has become infected during the operation I sew up the peritoneum with cat-gut suture and only a portion of the wound in the structures external to the peritoneum and drain the wound outside the peritoneum. Experience has taught me that a limited amount of infection will be safely disposed of by the peritoneum and that the open tissues of the wound afford a good culture medium for germ infection if buried under the skin. By separating the limited amount of infection within the peritoneum from the unlimited degree of infection in the other wounded tissues we obtain much better results than if the infected wound were in open communication with the abdominal cavity, and many of the objections to through drainage are eliminated.

DR. LOUIS C. AGER, Brooklyn—I am not a surgeon but only a pathologist, and I want to speak on the question of diagnosis. I have a specimen of perforated small intestine which I think will interest the surgeons. The diagnosis was appendicitis and the appendix was removed. The specimen is of interest because it shows the condition of the appendix at the time of operation. The patient died a few hours after the operation, and the autopsy showed that an apparently normal intestine had been perforated by a lumbricoid worm about eight inches above the appendix, causing septic peritonitis and death.

DR. JOHN B. MURPHY, Chicago—I did not expect to discuss this subject on this occasion as it seems to be rapidly coming to a solution, notwithstanding the apparent difference between the two doctors in reference to the various methods. We have come to the conclusion to-day more unanimously than ever before in this Association that the time for the operation is within the first thirty-six hours. We are agreed on this as medical men; we are agreed on it as surgeons. If we are agreed on this one point, stop there. One gentleman has put the proposition, what does the physician do when he gets appendicitis? He sends for the surgeon, and he sends within an hour or two of the time he gets the pain. Can we as medical men, can we with practical uniformity, make the diagnosis in that period? Yes, it can be done by the medical man, and it is no longer necessary to get a surgeon to make a diagnosis of appendicitis. The time to send for the surgeon is immediately after the pain develops. I am glad to hear Dr. Ochsner take the position he does. We can, and should, avoid the mortality of 15 per cent. or even 4 per cent., and we can do so by diagnosing early, operating early and recognizing early the conditions present. Good operators within the limited period prescribed by Drs. Deaver and Ochsner prevent this mortality. If this is true what is our action? Just the same as it would be if a building is on fire, put the water on it now—not to

morrow. Will you do an operation that might be avoided? Yes. Will you do an operation where the appendicitis can not recur? No. That patients do recover without operation no one can deny. The mortality should be reduced to one-half of 1 per cent. The diagnosis can be made early. If the saving of the lives of people is entrusted to us we have one thing to do and that is to act within the limited time.

DR. W. J. MAYO, Rochester, Minn.—I had said that I would not discuss appendicitis because it seemed to me this discussion often led to more harm than good, but I want to put myself on record as believing in the early operation. I believe that every attack of appendicitis, even if recovered from, calls for operation. If a patient has appendicitis and you can get him early he will almost surely get well from the operation, barring accident. The operation should be performed at once and the results will be almost uniformly good. When it comes to actual conditions there is a class of cases that comes to the surgeon when the most favorable time has gone by. Some years ago I operated on all cases at the time they were admitted to the hospital, and my mortality was from 12 to 15 per cent. This mortality took place in cases that came into the hospital in bad condition from the third to the fifth day. They were tympanitic, with a tendency to vomit, and showed symptoms of obstruction of the bowels. In those cases I had a considerable mortality. Taking the plan of treatment adopted by Dr. Ochsner I dropped my mortality from 15 per cent. to less than 4 per cent. I do not believe that we should let all of these cases come to the operating table right away. I simply say that in such a case the stomach should be washed out and food absolutely prohibited for from 24 to 48 hours, by which time you will be able to deal with these cases with comparative safety. I have lost two cases by waiting too long. I would, therefore, limit this treatment to a certain class that has furnished a large mortality; cases that you fear will die, but I would operate on them in from 24 to 48 hours, or as soon as it appears that the condition will warrant it. It is in these cases that previously I had my mortality, and by a radical operation not only was there the death rate mentioned, but also a high percentage of fistulas. I can only say that since I have changed my time of attack and handled these cases more gently I have had fewer deaths and a fistula is rare.

DR. JACOB FRANK, Chicago—I shall confine my remarks to one point in Dr. Ochsner's discussion. He stated that if the stomach was kept entirely empty and nourishment given by the rectum, it would prevent peristalsis of the bowels, thereby preventing further infection by extension. On this theory, I believe he bases his successful treatment of certain cases of appendicitis. If I am correct in this statement I must beg to differ from his views, and shall give my reasons for doing so: In 1883 I published a case in the *Correspondenzblatt* where rectal alimentation produced a retrostalsis, and the patient vomited the food injected; this occurred several times in the same individual. After this I made observations on dogs, and could produce the same symptoms in a certain number of them. In *THE JOURNAL of the American Medical Association* for 1901, p. 429, a very instructive article by Albert Bernheim, M.D., of Philadelphia, will be found, where he made observations on the human and on animals concerning retrostalsis. I know that many operators will agree with me that even a little water injected into the rectum in many cases produces vomiting, and general practitioners have often observed patients who became nauseated from a small enema. I have often observed patients get a violent colic from a small amount of fluid. In order for the Doctor to prove his theory he will have to disprove the fact that a retrostalsis can take place from injecting food into the rectum.

DR. DEAYER, in closing—I am glad and sorry that I have had such an extended discussion. I was going home on the 5:20 train, but I could not possibly leave Saratoga under these circumstances without replying to the distinguished gentlemen who have kindly discussed my paper. I agree with Dr. Abbe as to the pathology. It resolves itself into a question of drainage. Dr. Gibbons has brought the subject out very clearly, and it is very interesting to note that he has advanced views on this subject. I recollect distinctly something of Dr. Stillé's idea on

idiopathic versus traumatic peritonitis. I do not understand all of Dr. Ochsner's statements. I do believe, however, that he does not get the class of cases I do. You may say that can not be, but I look into my bellies and know what I am dealing with, while Dr. Ochsner guesses at what is going on. I have recently returned from a trip to Berlin, and while there I understood that Sonnenberg claims that he could differentiate between acute catarrhal appendicitis, fulminating appendicitis, perforative appendicitis, the different varieties of peritonitis, etc. I can not agree with him, although this may be stupidity on my part. The more I see of appendicitis the less I know about it, and the more bellies I open the more impressed I am with my ignorance. The probabilities are that if I were to treat certain cases, on which I now operate, by starvation I might get better results, but I have not been so strongly impressed with Dr. Ochsner's argument to induce me to change. Personally, I have tried the treatment. Drs. Ochsner and Mayo may recollect my taking them into my receiving ward on one occasion and showing them an advanced case. This was one of the cases on which I would not operate. Dr. Ochsner suggested that I try his treatment when he thought the patient would pull through the attack. I did, and the patient died. Autopsy revealed a belly full of pus. So many of the cases coming under my care of this type, having been sick from five days to three weeks. Another thing that makes me think that there is a difference is because Dr. Ochsner gets no fecal fistula. I see fecal fistulae in a number of cases each year. A patient may have a fistula which will heal in time and he may have one which will not heal spontaneously. How Dr. Ochsner's treatment can dispose of general purulent peritonitis, peri-appendiceal abscess in connection with a pelvis full of pus: how Dr. Ochsner's treatment will prevent pressure necrosis from a collection of pus: how the treatment will prevent secondary abscess, pyelophlebitis, metastatic liver abscess, general sepsis, endocarditis and so forth, I am at a loss to explain, and as Dr. Ochsner has not explained and has made no mention of such pathologic lesions I have no hesitancy in saying that he sees an entirely different class of cases of appendicitis than I do. The class that he sees evidently get well by doing nothing. In the speaker's experience the pathologic appendiceal storm has spent its force within a comparatively few hours of the onset of the attack in the cases that do not recover practically by doing nothing; therefore, unless the treatment outlined by Dr. Ochsner clears up the debris and leaves the field of attack as it was before the storm, it can not possibly be of any specific service. In short, to accomplish that which he would make us believe it does, it must make the peritoneum capable of absorbing almost anything in the shape of pathologic debris.

Washing out the stomach and giving nourishment by the bowel where the stomach is irritable, I am sure most of us do both before and after operation; therefore, with this much of Dr. Ochsner's treatment I agree. I take exception to giving opium and to the use of antiplogistine or any proprietary agent; the latter I have seen on Dr. Ochsner's patients. I am very sure that the mortality of appendicitis will be increased rather than lessened by Dr. Ochsner's treatment. Not in Dr. Ochsner's hands, perhaps, but in the hands of those who are averse to early operation, thus giving them a pedestal from which to proclaim against the radical treatment.

DR. SMYTH, in closing—This has been a most interesting and instructive discussion, but the hour is so late I will say very little. Undoubtedly we must be guided by the experience of each other and by our own experience too. In my own experience both from operation or following operation I believe I have seen more cases where there is involvement of the general peritoneal cavity. In other words, the cases in which the pus was localized, no matter how extensive it was, they all recovered. I think we are all agreed that operation should be done in every case in the early stages. The question of difference now is in those cases which we do not see until about 36 hours have elapsed. Shall we operate on those cases at once or wait until about thirty-six hours later? I should not hesitate to wait a certain length of time could I be sure that the process would remain localized and the pus would remain as an

conception of why they came, and afterward console themselves with the idea that they must have been drunk at the time. In some instances, evidently, the most prominent early symptom is a sudden maniacal impulse to drink to stupor, and on recovery the trance condition begins.

Gourmands and wine drinkers of this type display most unusual conduct or paroxysms, associated with chills or profuse sweating followed by stupor, then the dazed trance state follows. A number of cases under my care have but indistinct recollections of events preceding their admission for days and sometimes weeks. To their friends their conduct was strange, but the general symptoms were not those of alcoholic intoxication, but rather of general stupor from some brain trouble.

In these trance cases there is not necessarily any sudden explosive symptoms, but more often a sequence of mental degeneration, noted by defects of reason and emotional instability. In these three classes nearly all alcoholic epileptics may be grouped. The paroxysms and explosions of nerve energy, also hallucinations and delusions, are probably always present. Acts of violence, homicidal impulses, sudden chills, followed by motor spasms and sleep, are most significant symptoms.

A number of inebriates suddenly develop delusional states which are commonly seen in nearly all epileptics. Delusions of grandeur or fear of sudden death from injury, passing off in a short time, are intimations of epilepsy. These symptoms following or associated with the excessive use of alcohol are still farther confirmations. There can be no doubt that alcoholic epilepsy is increasing. In a recent examination of two hundred cases over 50 per cent. showed well-marked symptoms of epileptoid states. Inquiries indicate the increasing frequency of convulsive symptoms, resembling epilepsy, and there can be no doubt that these symptoms are coming into greater prominence yearly.

ETIOLOGY.

In some personal studies made ten years ago epilepsy was noticed in 5 per cent., and obscure convulsive symptoms associated with inebriety were recognized in, at least, 10 per cent. more cases. In all not over 15 per cent. of the cases then studied exhibited symptoms of this condition. In the police records the number of convulsive spasmodic intoxications with strange symptoms of mania and sudden nerve explosions of conduct have been known to occur in over 50 per cent. of all the cases. They are termed delirium tremens cases in many instances and the convulsions which occur are all considered part of the alcoholism from which the patient is suffering. Many of these police-court cases with well-marked epileptoid symptoms die before the later stages of epilepsy are reached. It is a fact that has not been recognized that sudden and convulsive intoxications are very often followed by pneumonia and death. Pneumoparesis seems to be the special form of disease which follows. In the first class of epilepsies which I have noted, these sudden pneumonic collapses are very common. In the second class of dementia, cerebral hemorrhages and nephritis are also common sequences. Homicide and suicide are frequent in both these classes. In the third class of trance cases well-marked epileptic convulsions are more pronounced.

In both of the other classes epilepsy may appear in its classical forms and inebriety subside, or the use of spirits may continue in diminishing quantities. In all these cases acute inflammations of the kidneys, of the liver and stomach, may occur suddenly, followed by

death. Well-marked classical epilepsy, seen in an inebriate, is of short duration.

INFLUENCE OF COMPLEX ALCOHOLS.

The increasing prominence of these epileptoid symptoms in the inebriate of to-day is apparently traceable to the changed form of spirits used. While it can not be stated authoritatively that this is the most prominent cause, it is evidently very influential and responsible in a large degree for many of the symptoms which follow. Within a few years highly fortified and flavored alcoholic drinks have become very popular, such as bitters, vermouths, absinthe, cocktails, high-balls, champagnes and other high-sounding names for fortified and strong-flavored alcohols. These drinks are nearly always composed of new and cheap alcohols, and frequently wood-spirits and often whisky from potatoes and beet roots are used, depending largely on the price in the market. These alcohols are concealed by flavoring substances, such as bitters and syrups, the purpose of the dealer being to increase the profit and make the drink attractive.

When these different drinks are given to animals, well-marked convulsive phenomena follow. The intoxications are always sudden and paroxysmal. Champagnes resemble these drinks in their effects only the period of exhilaration is longer and more intense and the coma following slower and more profound. By these mixed drinks the blood is driven to the brain with great violence and vasomotor paralysis comes on early, in some cases resembling a shock from injury. The control centers of the brain are very quickly broken up and the degree of intoxication is marked and prolonged. The bitters, absinthe and cocktail compounds have a peculiar paralyzing action on the sensory and motor centers. This resembles toxic convulsions in the disturbance and explosive character of the symptoms. In club-houses and in high-class bar-rooms where these drinks are popular, the exhilarations and stupor following seem to have a direct connection with the spirits used.

Among the lower classes and in cheap bar-rooms the same convulsive class of intoxications with wild fitful manias and heavy stupors are seen. How far wood alcohol is used in these highly-flavored drinks can not be ascertained, but every year the production of this alcohol is increasing beyond the normal demand; and this excess, selling at half the cost of other alcohols, is used up in some unknown way. The cheap brandies and whiskies, no doubt, contain this form of spirit. The large importations of bitters and absinthes and their manufacture in this country are also evidence of the changes in the character of the drinks used. The cheap champagnes manufactured in this country, while less irritating than foreign drinks of this kind, are more largely used than ever. The physiologic effect is that of intense irritation, congestion and paralysis.

It is the form of alcohol that is dangerous, not the compounds mixed with it. In the experiments of Dumont's, in which various alcohols were given to dogs and goats, it was proven beyond doubt that complex alcohols were convulsive in their action, producing local as well as general paralysis. The more complex the alcohol the more dangerous it was. Beyond the influence of mixed alcohols in the etiology of these cases, there are to be considered the neurosis and psychosis, both from hereditary surroundings and bad living. There is in many cases predispositions for nerve explosions which makes the person more susceptible. This must be taken into account in estimating the symptoms.

DIAGNOSIS.

The diagnosis in these cases is usually not difficult. While the general toxic states are alike differing only in minor particulars, there are sometimes very striking variations which have apparent connection with causes that are known. It is evident that the patient who drinks quantities of mixed alcohols and develops epileptoid symptoms is suffering from some form of toxic concussion, manifested in this way.

In other instances, the accumulation of toxins, formed both within and without the body, concentrate on the nerve centers, producing explosive symptoms. The masked cases are always difficult to determine except from a careful study of the habits and surroundings of the patient. The sudden onset of strange, unusual symptoms suggest epileptoid conditions. The excessive use of spirits preceding the paroxysm or fit are always significant hints of this condition. In a recent case under my observation, a moderate drinker after two glasses of champagne became delirious, maniacal, and while walking to his room had a distinct convulsion. This was the culmination of a long premonitory period in which the toxic symptoms showed the tendency to take on this form.

PROGNOSIS AND TREATMENT.

The prognosis is always grave and unless the alcohol is removed at once the prospect of intercurrent disease or death or pronounced epileptic symptoms is very serious.

In the treatment, total abstinence from all spirit compounds with brisk elimination, restricted diet, nerve and brain rest continued for a long time give the only hope of restoration. Often a radical change of business and surroundings is most essential for successful treatment.

SUMMARY.

Some of the facts I wish to make prominent are:

1. Alcoholic epilepsy is increasing rapidly in this country.
2. It is a psychosis and neurosis which should be recognized, having distinct symptoms, the recognition of which is imperative in the treatment.
3. Where the toxic symptoms are convulsive and explosive and come on suddenly, the future of the case is very ominous and the warnings from these symptoms should be heeded.
4. The connection between mixed drinks and these spasmodic symptoms are traceable and should be considered in the prognosis and treatment.
5. The treatment and curability of these cases can be carried on with great hopefulness, and undoubtedly in the future will become a prominent part of the work.

DISCUSSION.

DR. C. H. HUGHES, St. Louis—I do not agree with all that Dr. Crothers has said on the subject, among other things being his assertion that the sudden onset of alcoholic epilepsy is the gravest form of the disease. The first case of genuine alcoholic epilepsy that ever came under my observation, outside of a lunatic asylum, occurred for the first time in an individual who was on a drunk. It was the first attack of this kind that he had ever had. He was seized just as Caesar was in the market-place at Rome, although he sat at the drinking table and fell under the table, convulsed and unconscious, and with frothing at the mouth, and the usual sequelæ of a well-established case of severe epilepsy. I was interested in that case, of course, because I saw it in its inception, and I then for the first time knew of alcoholic epilepsy. I wondered if the man were going to become a constitutional epileptic. I did not know so much then on the subject as I do now. I had not then

been superintendent of an insane hospital, as subsequently I saw several hundred patients daily. I was then a young army surgeon, not 22 years of age. I took this man, who was a personal acquaintance of mine, to my hospital and took care of him and nursed him through the paroxysm. He went to sleep after the paroxysm had passed off and he slept in the hospital until the next morning, when his recovery seemed complete. I have watched that man ever since and he is living to-day and has filled some important positions in life. To my knowledge, he has never had any similar attacks. He has modified his habits of drinking. I told him exactly the condition he had been in, and I think I frightened him into a better life. This was purely a case of alcoholic epilepsy. Of the existence of this form of epilepsy I have never since entertained a doubt. Alcohol is a most potent causative and developmental factor in the generations that immediately succeed inebriate lives. The tables of Mognan and others have clearly established this.

DR. J. P. McBRIDE, Los Angeles, Cal.—I recall a case of this condition in a young man about 25 years of age, who was a very light drinker. About once a year he would go on a drunken spree and he always had an epileptic attack during the continuance of this condition, which would usually last from three to four weeks. During the intervals between these sprees he never had any attacks. At the age of 26 he suffered from delirium tremens and died, and during this last spell of drinking he had suffered from very frequent epileptic attacks. It has occurred to me to ask the Doctor what has been his experience in this line and whether, if these cases abandon the drinking habit they get well or if some of them get well, and about what proportion.

DR. JAMES H. LLOYD, Philadelphia—I think there is no subject more obscure, nor one about which we ought to dogmatize less than the subject of the etiology of epilepsy. I have listened to the paper of Dr. Crothers with a good deal of interest. I think we may admire Dr. Crothers's skill in psychologic analysis and I believe his large experience in this class of cases entitles him to respect and deference; yet in some ways I hardly feel like following him in all that he has said. In the past I have had relations with hospitals containing large numbers of epileptics; I have seen a great number of them, but I have never quite assured myself that there was any distinct form of epilepsy that could be called alcoholic epilepsy. I grant, of course, and we all know, that there are plenty of epileptics who are alcoholics; that there are plenty of epileptics who drink to excess, who get drunk; but that we have a distinct class of epileptics whose disease bears a relationship to excess in alcohol is a question, about which, as I say, I will not speak dogmatically, but about which I have always felt very doubtful. My feeling has been that we should regard alcohol as an exciting cause of epilepsy, a contributing cause, but not necessarily the essential cause. There are a great many things that will cause a convulsive attack; for instance, uremic poisoning, the poisoning which occurs in the pregnant woman, an injury to the brain, the poisoning of scarlet fever or the effects of some other diseases; all these act as exciting causes of convulsions, but we do not say that we have a uremic epilepsy; that we have a scarlet fever epilepsy, etc. We know that these factors act on the nervous system and produce epileptic attacks. My belief is that that is practically what we have in the cases of alcohol producing these epileptic attacks. In other words, I think if you take a man who is perfectly normal, who has no distinct tendency toward epilepsy, you can not make an epileptic out of him by making him drunk. If this could be done, I think a good many more of the American population would be epileptics. You can not make epileptics out of inebriates, but you can make inebriates out of epileptics; and that is a very different thing. There is a tendency in certain forms of epileptics to become inebriates; it is a part of their degeneration; it is a part of their run-down nervous system. After the onset of the epileptic attacks, they may take to drinking and the epilepsy in that case acts as a predisposing cause of their drinking, as much as alcoholism is a producing cause of epilepsy. It is hard

to say which has occurred; it is hard to decide which began first. I think we must consider this matter carefully and not dogmatically. This whole subject has to be settled with the greatest accuracy and care, and I am not certain that we have yet at hand the method or the knowledge that will permit us to say positively that we know what is the cause of epilepsy. I feel that this is an important question, because, as neurologists assembled here, we do not want to put ourselves on record too absolutely; we want to leave our minds open in reference to this whole subject.

DR. J. M. KENISTON, Middletown, Conn.—In reply to the question asked by Dr. McBride, I might state that in Middletown we have had a number of cases where the epilepsy has arisen in the victim of chronic alcoholism, and in these cases the symptoms did not disappear on the removal of the alcohol. The seizures are apt to be rather infrequent, from 4 to 10 yearly, some of the cases having remained without attacks for a year or more. My experience has been somewhat limited in these cases, and has been confined entirely to male epileptics. I feel from my experience that there is rather more of a tendency to dementia in this class of cases of epilepsy than in any other, and that moral indifference is one of the inevitable sequels of alcoholism. The onset of all my cases occurred in late middle-life.

DR. A. B. RICHARDSON, Washington, D. C.—I agree that the class of cases the Doctor's paper describes are found in the experience of all of us, and the only question I shall raise is in regard to the interpretation of them, and in regard to the erection of this new form, or rather special form of epilepsy called alcoholic epilepsy. I think he will agree with me that the class of cases he describes arise also from other causes as well as from the excessive use of alcohol. Take, for instance, the acute forms of the disease—they are frequently produced by other causes and, in fact, I recall but very few cases where they could be attributed to excessive use of alcohol. Now, I think it is always better to keep our classification of disease just as simple and practical as possible. In any case addicted to the use of alcohol, especially where the use has extended over a long period of time, occasionally you will have convulsive attacks. Should all of those attacks be called epilepsy? I do not suppose that the Doctor would agree that they should be so called. As the last speaker has stated, convulsive attacks, of course, occur in a great many diseases. The excessive use of alcohol acts as an irritating cause in some manner or other to produce these epileptiform attacks. I think we all agree that occasionally the excessive use of alcohol may produce a typical epileptic attack. But we have a great many other causes also, and you may as well call every one of these a typical form of epilepsy. The question is whether, as our knowledge is at present, the condition which he has described is peculiar to this cause of the disease. I think we ought to restrict the term "epilepsy" to that form of the disease which is permanent in its manifestations and frequent in its occurrence, and not apply it to convulsions which come on from irritating causes now and then.

DR. WILLIAM J. HERDMAN, Ann Arbor, Mich.—I think we all recognize the fact that chronic alcoholism may play a part in the production of these epileptic convulsions, just as it acts as an agent in the production of dementia. There is in all these cases due to chronic irritation a mental reduction which undoubtedly is structural in character. Now, as has just been said, that reduced structural condition can be brought about by many other causes than alcohol. We recognize a great many other causes producing it aside from alcoholism. It would have been very interesting to me if the Doctor had added to his paper some information concerning the previous history of these cases. Some of them were evidently cases of acute alcoholism; others were cases of chronic alcoholism, but if in all of them he could have given us evidence of hereditary alcoholism in their ancestors, it would have enabled us to arrive at conclusive decisions along the lines with which we are all familiar. These cases of chronic alcoholism in many cases terminate in epileptic manifestations. I do not recognize in the description he has given of these cases that they were different in any particular from the epileptic attacks due

to other causes and, therefore, that does not justify a separate classification, and as has just been said, if we should put into a separate classification each case of the condition according to the factors producing it, we would have a great many more classes of epilepsy than necessary.

DR. RICHARD DEWEX, Wauwatosa, Wis.—We know that it is a striking fact regarding this class of cases (of which I have happened to see a large number) that in some cases the epilepsy or any convulsive manifestations have not been present, so far as one can learn, at any other time, except in conjunction with alcoholic excess. There seemed to be no convulsive attacks except when the individual was heavily under the influence of alcohol, and the number of attacks was frequently very small, in some cases occurring but once or twice in a lifetime. Then again there are other individuals who have never used alcohol to excess who have had but a single attack in a lifetime, or perhaps may have had two or three attacks in a lifetime; this makes the matter more obscure. One other point: the cause to which Dr. Crothers has referred, of a toxic effect being produced by the use of an inferior class of spirits, especially wood alcohol, would not apply to all cases, for I have seen cases largely where the patient used only a very good quality of spirits.

DR. F. SAVARY PEARCE, Philadelphia—The subject is most interesting and I will simply detain you for a few moments in regard to the treatment of these attacks. I believe that a good many of these attacks or epileptic phenomena are due to congestion of the brain itself and, even when the patient is in an acute alcoholic state, he has, of course, a congestion of the brain. I had under my care only a few days ago a gentleman who has a very good past history in every way. He was suddenly taken during the recent warm spell with a typical attack of epilepsy. I saw him when he was in the third convulsion which he had had during four consecutive hours. The sphincters were intact except in the third convulsion; and it was a typical case of epilepsy as regards all three of the convulsions. I promptly bled the man, withdrawing over a pint of very dark blood, which seemed to be the most rational form of treatment. The man improved at once and in a week he was apparently well. I believe that this form of treatment is the proper method whether alcohol is the cause of the attack or not. In this condition the brain congestion itself at the moment is responsible for the epileptic phenomena.

DR. HUGHES—I want to ask the Doctor if he will, in his reply, kindly explain what he means by the statement that the treatment of one of his cases was changed to the bromids and then bromidism followed, resulting in death. Then, I would like him to explain what he means by the term alcoholic epilepsy being a new one to the literature. I have in mind the fact that Esquirol, before I was born, claimed that many of the cases of epileptic insanity are due to alcoholism, and in discussing the subject of epilepsy he speaks of the excessive use of alcohol as being one of the causes of the development of a form of epilepsy associated with insanity. Then, the conditions of double consciousness mentioned and the automatic states are also referred to this same cause. In dementia, what we call "alcoholism" now, but which was called "inebriety" then, was commonly known as the cause of this condition. I would like to know the number of cases in which the epilepsy developed where there was reason to suppose that there was epilepsy in the family and the manifestations were brought out by the alcoholism, and the other cases where it was produced solely by the alcohol. In the case that I mentioned there was no history, and when the drinking subsided the epilepsy did not recur. I think that Dr. Crothers has had a peculiar kind of experience; he has had an experience with alcoholic epilepsy without the insanity and this is especially valuable from the standpoint of insane asylum physicians.

DR. T. D. CROTHERS, Hartford, Conn.—In my regard, alcoholic epilepsy is simply a name and not a distinct disease. We do not know anything of the pathology of epilepsy and can only speak of it as a form of degeneration possessing symptoms more or less uniform. There is no true division of

these symptoms in the alcoholic from other cases, because there is such a multiple of causes. We can only take the excessive use of alcohol as one of them. It is not a distinctly new term, but it has many symptoms which seem to be peculiar and common to it. Most of these symptoms indicate a toxic condition. Epilepsy is often a toxic and convulsive state. Alcoholic toxins and other causes are likely to produce this state. We know that epilepsy is one of the active causes of insanity. The term alcoholic epilepsy is practically new. Ten years ago the term was seldom used, while to-day it is frequently mentioned. Many of the toxins may produce symptoms which resemble alcoholism. Epilepsy, alcoholism, morphinism, dementia, consumption, sudden collapse and hemorrhage of the brain may all follow from the presence of toxins. The symptoms will change widely. There are some cases which could be attributed solely to the use of alcohol, but even here some long predisposing causes are at work, usually some diseased state of the neurons, some former degeneration existing before the attack. Such persons nearly all die from acute nephritis or cerebral hemorrhage. Then, it is another point of clinical interest, that is that the use of the more toxic alcohols produce symptoms which resemble epilepsy. These are active causes which in modern times are very prominent. Concerning convulsive alcoholism, convulsive epilepsy and convulsive disease of the brain, it is a striking fact that these symptoms are becoming more common, and I think that a great many of them can be directly attributed to the use of the mixed drinks to which I have referred. If the police court records of drunkenness with convulsive symptoms were examined, many of them would be explained by the term alcoholic epilepsy.

THE PATHOLOGY OF CHROMIDROSIS.*

M. L. HEIDINGSFELD, Ph.B., M.D.

Professor of Dermatology, Laura Memorial Medical College; Clinical Lecturer on Dermatology, Miami Medical College; Dermatologist to the Presbyterian and Jewish Hospitals
CINCINNATI, OHIO.

The name chromidrosis implies an anomalous secretion from the sudoriferous or sweat glands characterized by colored perspiration. Its occurrence is exceedingly infrequent; Foot,¹ in a careful review of the literature dating from 1709 to 1868, has been able to enumerate but 38 cases, to many of which a doubtful character must necessarily be attributed. Fowie's² careful historical review. 1709-1891, does not add many well-defined cases, and surprisingly few have been reported in the literature of recent years. Its marked infrequency can be best appreciated by referring to the Van Harlingen's³ statement, that "it is so rare as to be a curiosity rather than a disease."

Those who have written on the subject, almost without exception, are of one accord as to nature, and attribute to the condition a disorder, functional or otherwise, of the sweat glands. This is especially evident in all the text-books of skin diseases, where the subjects are not alphabetically arranged and follow some system of classification (Hyde,⁴ Hardaway,⁵ Morrow,⁶ Kaposi,⁷ Duh-ring,⁸ Joseph,⁹ Stelwagon,¹⁰ Shoemaker,¹¹ Schamberg,¹² Fox,¹³ Gottheil,¹⁴ etc.); in these the affection is invariably classed with the anomalies of glandular secretion, namely, the sudoriferous glands, and is grouped with hyperidrosis, anidrosis, bromidrosis, uridrosis, hemati-drosis, etc. In those which follow an alphabetic arrangement an anomaly of secretion is, as a rule, directly attributed, or indirectly implied (Jackson,¹⁵ Van Harlingen,¹⁶ etc.), apparently a few (Lesser,¹⁷ Mracek,¹⁸ Bulkely,¹⁹ Neumann,²⁰ etc.), studiously refrain from

committing themselves. It is surprising that some of the earliest observers (Nelligan, Wilson and Gintrac) have attributed the condition to a stearrhea, and Turenne to a metastasis of the eye pigment, facts which seem not so remarkable when we consider that the early investigators were very keen observers and relied almost exclusively on their powers of personal observation.

The color of the secretion varies with different cases. green, blue, purple, black, brown, yellow, red and intermediate shades. Black is the most common occurring in one-half the cases reported by Foot. Cases characterized by red pigmentation are generally associated with a reddish incrustation of the adjacent (usually axillary) hairs, the bacteriologic examination of which reveals the condition to be due to a *Zooglea* (*Bacillus prodigiosus*), which grows in rose-red colonies and often gives a history of direct contagion. These cases can not be properly classed with the so-called chromidrosis, but belong, by nature, with greater propriety to the class of so-called vegetable parasitic affections of the skin.

In my own clinical and private practice I have noted eight cases of this so-called red chromidrosis during the

Fig. 1.—Hyperkeratosis in opening of hair follicle. Accumulation of pigment in rete, P and P'; in corium, P'', and stratum corneum, P'', of immediate neighborhood. (Winckel, oc. 2, obj. 5.)

past two years, in most of which there was not only a reddish discoloration of the incrustated hairs, but also distinct reddish discoloration of the superimposed garments. If this class of cases is included, chromidrosis is by no means a rare affection, and it probably falls to the lot of nearly every close observer to note these cases from time to time. At present I have, among others, two patients under observation with this form of affection, an uncle and nephew, the latter of whom is a practicing physician, who has taken up his residence with his uncle during the past four years. The physician states that his infection is of five years' duration, and that his mother, with whom he then resided, is similarly affected, and has had her affection for almost the same length of time. His uncle acquired the affection almost four years ago, and more recently his daughter has also been infected. The axillæ in all the cases have been involved, and all the cases show the red discoloration to a marked extent. From these and other cases in the literature it is clearly evident that these forms of reddish discoloration are readily contagious, and owe their cause to a local infection, entering from without. Their para-

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. W. T. Coilett, L. Duncan Bulkley and W. L. Baum.

sitic nature is further evidenced by the fact that some of my cases of so-called red chromidrosis have readily yielded to a few applications of Wilkinson ointment.

Though nearly all who have reported cases of red chromidrosis have attributed the cause to a parasite, different authorities vary as to its true nature. A few (Labrares et Cabannes²¹) strongly deny its bacteriologic nature; Temple²² attributes it to the ingestion of potassium iodid; Stott,²³ to torulæ, which grow in rose-red colonies on potato culture at 38 C, and deep red at 0 C; Fowie²⁴ ascribes the cause to the *Bacillus prodigiosus*; Babesi²⁵ to a form of *Zooglea*, and Hartzell²⁶ to a fungus bearing a resemblance to the *Micrococcus tetragenus*. This marked diversity of opinion induced me to make culture experiments on potato, gelatin, agar, etc. Potato cultures served the best, and though contaminations were very common, involving different forms of sarcina, staphylococci and bacilli, deep brick-red colonies could be isolated in most instances, whose microscopic appearance was a *Micrococcus tetragenus*. Inoculation experiments were not attempted.

Let us now digress from the so-called cases of red chromidrosis and resume with the more well-defined

colored. The coat sleeve lining shared in the discoloration to such an extent that its renewal, for cosmetic reasons, every two months, became a necessity. The patient was able to take note of no other subjective or objective symptoms of any character whatever. The condition has persisted continuously for the past two years. Perspiration has not been excessive and to the patient's knowledge but slight.

When patient presented himself for examination, for the first time on March 5, 1902, the skin over the affected wrist was apparently normal; there was no evidence of any inflammation, and no disturbance of innervation. Compared with the skin elsewhere on the body and with the opposite wrist, there was a very slight, evenly-diffused pigmentation, as if the affected area had been lightly bathed with tincture of opium. It remained unchanged when scrubbed with pledgets of cotton dipped in water, soap, alcohol and ether and the pledgets themselves took on no discoloration. Pledgets dipped in chloroform removed the discoloration rapidly and left the areas thus treated much whiter by contrast than the surrounding area.

Examination of urine showed reaction faintly acid, no albumin, no sugar, no formed elements, specific gravity 1020 and no indican. Blood examination by Dr. Alfred Friedlander showed no variation from the normal.

An examination of the secretion, which was collected on pure white linen, revealed it to be insoluble in the ordinary solvents,

Fig. 2.—Two circumscribed accumulations of pigment in rete, and corium, P and P. (Winckel, oc. 1, obj. 3.)

cases, in which, according to Foot,²⁷ 34 out of 38 were women, 19 out of 29 were unmarried, age varied from 5 to 57 years, average being 22 years; the face, particularly the eyelids, is most commonly involved and uterine disturbance and hysteria are frequently associated. In nearly all the cases the attack comes on suddenly without apparent cause, and persists usually for a few years in intermittent form.

The case which I wish to report occurred in H. O., a brunette, a native of Germany, aged 53, a merchant of intelligence, good social standing, who has been married for 15 years and is the father of one child. His general health has been excellent; in 1898 he suffered with an attack of hepatic colic, which was followed by jaundice, and the following year, under severe medication, involving salivation, he passed a large number of gallstones. In a short time he regained his customary good health, which has been uniformly good since 1900. In 1901, he noted for the first time that the linen of his right forearm became discolored. The discoloration was a yellowish-brown and permanent in character, so that it could not be removed in the process of laundering. The discoloration was rapid and extensive, so that in two days' time a new cuff or a new shirt sleeve was very perceptibly and indelibly dis-

Fig. 3.—Circumscribed accumulation of pigment, P, within the rete malpighi. (Winckel, oc. 2, obj. 5.)

ether, alcohol, water, glycerin, zylol, etc., and readily soluble in chloroform, imparting to the latter a yellowish-brown color. Hydrogen dioxid exerts no bleaching action on the yellow color. When evaporated on glass slides it formed a smooth yellowish substance, which under the microscope revealed a semi-crystalline appearance, due no doubt to the admixture of old, dried-up epithelial cells and other detritus (Fig. 5); when previously filtered, the microscopic appearance is amorphous and structureless; when the chloroform is completely evaporated, the deposit retains a resinous character, readily taking the impression of the finger and showing with minuteness the folds and furrows of the skin, or can readily be etched by means of a needle.

The eliminated substance is unaffected by acids (nitric, hydrochloric, sulphuric, carbolic), and fails to give the characteristic reactions for indol, indican and bile pigments. The negative character of these reactions and the absence of indican in the urine is sufficient evidence, I believe, to dissociate this affection from renal and hepatic predisposing influences, notwithstanding strong opinions to the contrary (Labrares,²⁸ Hofmann²⁹) and the preëxisting liver disorder in this particular case.

On March 8, a small piece of skin was removed from the anterior surface of the wrist, near the ulnar border, central

to the area of greatest discoloration, for the purpose of microscopic examination. It was thoroughly washed for one-half hour in running water and hardened in successive alcohol; the use of formalin, Müller's fluid, etc., was purposely avoided, in order not to induce discoloration, or to conserve the blood, and thereby mask pigmentary changes. The preparation was imbedded in celloidin and sectioned in successive serials, and examined partially unstained and bleached, partially stained with polychrome-methylene-blue, eosin, hematoxylin-eosin, hematoxylin-picric acid, Van Gieson, thionin, orcein, etc. The unstained specimens and those faintly stained with polychrome-methylene-blue (Unna), decolorized with glycerin ether, showed the most interesting changes.

My interest was first centered in the microscopic appearance of the sweat glands; they are found to be normal, showing no cystic dilatation, no pigmentary infiltration, no discoloration and no inflammatory changes. In other words, no pathologic alterations, no structural variation from the normal can be detected in these elements, which, in any manner or form can induce, or result from, a so-called chromidrosis or colored sweating. (Fig. 5.) This finding accords with what would be naturally inferred from the nature of the pigmented elimination, the latter being thoroughly insoluble in

which have been previously bleached with hydrogen dioxid, or specimens which have been very faintly stained with polychrome methylene blue, and decolorized with glycerin ether. Many are located in external layers of the stratum corneum, exclusively in and around the hair follicles, and particularly those areas which show the above-mentioned hyperkeratosis. The greater quantity is distributed to the lower layers of the epidermis of those areas, where the pigmented bodies are accumulated to form compact masses, occasionally showing a central cavity and often distinctly walled off from the surrounding tissues. (Figs. 2, 3 and 4.) The lower layer of columnar or germinal cells of the epidermis of this region show marked pigmentation, pigment of the same form and color, as described above, and contrasting strongly with the pale germinal cells situated elsewhere along the epidermis.

In and around the papillæ, extending for some distance into the corium, and in close proximity to the hair follicles, adjacent to the pigmented germinal cells of the epidermis, are numerous small pigmented bodies, for the most part roundish, but often irregular in outline and retaining the same general analogy to the above-mentioned

Fig 4—Circumscribed accumulation of pigment, in corium, with a central cavernous space (Winckel, oc. 2, obj. 5.)

water, could scarcely be eliminated by a secretion essentially watery in character.

The general appearance and structure of the skin is almost normal. The epidermis, corium and subcutaneous connective tissue are normal in their general structure and contour. The stratum corneum, rete mucosum, papillæ, capillaries, ducts of the sudoriferous glands, show no marked variations from the normal. A marked hyperkeratosis is present around the opening of the hair follicles, and the adjacent stratum corneum is thickened to two or three times the natural size. (Fig. 1.) Associated is the entire absence of sebaceous glands. Although hair and their follicles were abundantly present, and innumerable specimens were carefully examined, not the vestige of a sebaceous gland was discovered in any of the specimens. Elastic fibers, though abundantly present, showed no marked variation from the normal.

Examination with the higher powers of the microscope readily show the presence of small, roundish yellowish particles, which for the most part are located in definite areas of the specimens. They can be most easily detected in unstained preparations, particularly those

Fig 5—Showing normal condition of the sudoriferous glands. (Winckel, oc. 2, obj. 5)

pigmented bodies. The latter cells have an analogy to the so-called chromophore cells, which are believed to bear the pigment of normal cells from its origin in the cutis to the epidermal cells. They retain the same localization, and apparently perform the same function, the distribution of pigment from the cutis to the epidermis. They differ, however, materially in certain characteristics. They are smaller and more roundish in outline, and show no long proto-plasmic processes, so-called pseudopodia, by reason of which these cells were for a time supposed to possess ameboid movements and carry the pigment from its point of emanation to the epidermis. Ballowitz³⁰ has been able to demonstrate that the nerve endings penetrate these cells and envelope them thickly with dichotomous branches, thereby precluding their movement. He has also been able to demonstrate in the scales of fresh herring that the apparent change of form is due to the transposition of the pigment (which in the chromophores is finely granular) within the cells. The chromophores therefore probably serve as mere "stepping stones" or fixed carriers for the pigment in its course from the deeper structures to the sur-

face. The pigmented bodies in chromidrosis differ from the chromophores of ordinary pigmentation, in that their contents are not finely granular, but homogeneous and amorphous, and that they do not decolorize with hydrogen dioxid.

I was unable to determine to my personal satisfaction the ultimate source of the pigment in chromidrosis. That its source is from some point in the cutis is readily apparent from the examination of the specimens, but whether it springs from lymph or blood vessel, from pre-existing cell tissue, or what not, will be equally if not more difficult to determine, I believe, than the present unknown source of the pigment of the cutis. Its apparently free dissemination in the epidermis, tissue pre-eminently vascularized by lymph, leads me to concur with Moritz Cohn.³¹ that the pigment is derived from the lymph spaces of the cutis.

I regret that I have been unable to discover in my investigations into the literature any report on the histologic changes in any of the cases thus far recorded, inasmuch as a comparison would have been of great interest and confirmation of great value. No mention of chromidrosis is made in Unna's³² "Histopathologic

or predisposing cause. He is of a temperate, phlegmatic disposition, quiet, unobtrusive in nature and had noted the affection over a year before he became sufficiently interested to bring it to the attention of a physician. Simulation has been carefully ruled out by applying a coating of zinc gelatin to the affected area, after a previous application of chloroform, although there were little grounds for entertaining any suspicions. He is not addicted to drugs (Temple³³), vocation (Dyer³⁴) and trauma (Geschelin³⁵) exerted no predisposing influence, and he is not neurotic (Fowie,³⁶ Foot³⁷), parietic or epileptic (Delthil³⁸).

A case of simulation came to my notice in June, 1900. Miss R. F., aged 22, from Van Wert, Ohio, was consulted in regard to a reddish discoloration of the left palm and forearm, associated with shred-like desquamation of two years' duration. The case elicited much local attention and the diagnosis of erysipelas and a suggestion of amputation induced the parents to seek special advice. Red chromidrosis or simulation promptly suggested itself, and a two weeks' stay in the hospital with a plaster-of-paris bandage cleared up the condition and confirmed the latter diagnosis. A confession from the

Fig. 6.—Concretion attached to a hair, from a case of red chromidrosis (Oc. 1, obj. 3, Winkel.)

Fig. 7.—Structural appearance of the concretion attached to a hair, taken from a case of red chromidrosis (Oil immersion 1/12, oc. 4, Winkel.)

der Haut," a work that is very comprehensive as regards the pathology of the skin and replete in all its detail. One case is hardly sufficient, especially in a disease which shows so many variations, to serve as a standard for all, but its marked infrequency precludes the reports of accumulated cases.

With the hope that a spectroscopic examination may have been able to shed more light on the nature of the eliminated pigment, a chloroform solution was sent to Mr. C. P. Fennel, who has kindly reported that absorption bands were not present, and hence it was not a product of hemoglobin or oxyhemoglobin. Sodium bands, somewhat expanded, were present, together with two faint, narrow interposed lines, which could not be read with any degree of satisfaction. A careful chemical analysis has not been attempted, but for reasons above stated I do not concur that it is derived from indigo or indican, bile or hemoglobin. I believe, for the present, it can be classed with due propriety with the large class of pigments of the body, the nature of a large number of which is, as yet, so little known and imperfectly understood. I am unable to attribute to my case any direct

hysterical young woman then revealed that she had been in the habit of applying crude carbolic acid locally and tinting the member with artificial rose petals dipped in water.

I have been unable to carry out any prolonged line of investigation in regard to treatment. It is somewhat difficult to suggest proper curative agents, and the same futility as regards treatment no doubt presents itself in this disease as in chloasma, vitiligo and other pigmentary disturbances. I have found that sponging the affected surface locally with chloroform is an excellent palliative measure and prevents the excessive staining so disagreeable and annoying to the patient.

To recapitulate, chromidrosis is not, as its name implies, an anomaly of sudoriferous secretion. Judging from the limited number of cases in the literature, and as a matter of common observation, it is an exceedingly rare affection as regards forms characterized by yellow and brown, and probably black, blue, green and intermediate shades of discoloration. Red chromidrosis is an entirely different and by no means an infrequent type

of affection, with an extraneous cause, probably some form of erythro-micrococcus-tetragenus infection from individual to individual, and yielding to antiparasitic remedies. In the light of this investigation the pigmented elimination, in the yellowish-brown forms at least, is insoluble in water, alcohol, ether, etc., is readily soluble in chloroform, stains linen indelibly, shows no reaction when treated with ordinary reagents, and is amorphous, homogeneous and resinous in character. Pathologic examination reveals the sudoriferous glands of the affected area to be normal, sebaceous glands absent, a hyperkeratosis around the openings of hair follicles and pigment accumulations near the hair follicles, in the stratum corneum, lower layers of the rete, and the adjacent cutis. The pigment is grouped in cell-like masses, is not finely granular and does not bleach with hydrogen dioxid like chromophores. Spectroscopic examination of the eliminated pigment reveals no absorption bands and hence it is not a derivative of oxyhemoglobin. In view of the pathologic findings, the absence of sebaceous glands, the normal condition of the sudoriferous glands, cases of so-called chromidrosis (excluding red forms) are anomalies of pigmentation and not glandular secretion.

DISCUSSION.

DR. M. B. HARTZELL, Philadelphia—The so-called red chromidrosis of the axilla has nothing at all to do with the sweat glands, the sweat only dissolving the coloring matter of the masses on the hairs. While this affection is most frequent in the axillary region I have seen it on the hairs of the perineum. I recall a case in which I was not as successful as Dr. Heidingsfeld, although I saw the case at intervals for eight or ten years and tried everything to effect a cure. The woman's underclothing was stained a deep orange so that she was compelled to constantly change it.

DR. H. G. ANTHONY, Chicago—I hesitate to accept the pathology which finds the pigment a fixed tissue as well as being carried out through the sweat glands. The Doctor has said the sweat has not been subjected to a further chemical analysis. In the case which was subjected to chemical analysis the chemists and dermatologists found indican. Until such an analysis has been made I do not think he has a right to say that this cause is not due to the secretion of indican.

DR. W. S. GORTNER, New York—I confess it was not made clear to me how this pigment got to the surface. I would like to have some explanation.

DR. HEIDINGSFELD—I must confess my inability to satisfactorily explain the rôle which the pigment plays in the process of elimination. The source of the pigment and its conservation and distribution is an exceedingly obscure subject in not only normal conditions, but in the pigmentary changes more commonly encountered in vitiligo, chloasma, canities, pigmented nevus, sarcoma, etc., and it seems to me that some of my fellow members are requiring much from a condition which, at best, can offer relatively little. I dwell on the point of pigment elimination and pigment distribution as fully—and clearly in the paper as circumstances would permit. I believe that the process, to all appearances, is similar to the changes which accompany normal pigmentation, the pigment reaching the surface, from cell to cell through some form of stepping stone or carrier, from its source in the cutis. It can be traced directly by its presence, through the different areas mentioned, to its ultimate distribution in accumulated masses on the surface in the uppermost layers of the epidermis. I am firmly convinced that the sweat glands play no important rôle in this affection, as evidenced not only by their normal appearance and the pathologic changes in the other tissues, but also by the physiologic evidence of the insolubility of the eliminated pigment in aqueous solutions, which precludes its elimination from the sweat glands. Its insolubility in ether, alcohol, oil, etc., renders its elimination from the sebaceous glands also highly improbable.

THE BLOOD IN FILARIASIS.

W. J. CALVERT, M.D.

Pathological Laboratory, Washington University.
ST. LOUIS.

Since the discovery of the embryos of *Filaria nocturna* in the peripheral circulation by Lewis, in 1872, very few observers have devoted their attention to the changes in the blood associated with this disease.

In 1894 Bancroft and Bancroft¹ noted a leucocytosis in filariasis and published the following blood counts, no differential blood counts being made:

	Whites.	Reds.
Case 1.....	23,750	5,360,000
Case 2.....	12,000	6,000,000
Case 3.....	27,300	6,000,000
Case 4.....	21,500	6,000,000
Case 5.....	14,500	~ 4,600,000
Case 6.....	5,500	3,620,000

Lothrop and Pratt,² in 1900, found the whites in two cases to be about normal; their highest count was 8,000, lowest 3,500. Differential counts showed 4.6 and 3.5 per cent. of eosinophiles.

G. L. Gullard³ found a leucocytosis varying from 4,600 to 13,500, and an eosinophilia varying from 3 to 12 per cent. He observed the highest leucocytosis and eosinophilia when the number of embryos in the peripheral circulation was greatest; and a decrease in the leucocytes and eosinophilia accompanying the decrease of the embryos in the peripheral circulation.

A few months later Coles⁴ noted an increase of eosinophiles of 15 and 17 per cent. in smears made from cases of filariasis and bilharzia hematobia.

My attention was directed to this subject in the summer of 1900, while examining tissues removed at autopsy from a pest cadaver. A parent worm was found in one of the iliac lymphatic glands and numerous eosinophiles were noted in the capillaries of the several organs. (Case 1.) During the winter and spring of 1901, 426 specimens of blood taken from Filipino prisoners of war were examined. Two cases of filariasis were found.

CASE 2.—A. P.; male Filipino; native of Albay; has been in Manila about one month. No history of previous illness could be obtained. During past three months patient has had occasional chills and fever. Left iliac glands have been painful

two months, and the inguinal one month. Patient is a healthy-looking, well-built man.

Examination—Left conjunctivitis; pulsating veins in the neck; old variolar scars on arms; few râles and roughened breathing in right lung; heart dulness extended from 2 cm. to right of sternum to 2 cm. left of nipple line; area of pulsation from third to fifth interspace; sounds booming; liver and spleen normal in size. On the left side, immediately above Poupart's ligament, a painful tumor could be palpated. This tumor was, most probably, enlarged iliac glands. One inguinal gland was about three-quarters of an inch by one inch in size and painful. Both spermatic cords and testicles were normal.

Eight embryos were found in specimen of blood taken on April 4, 1901, at 11 p. m.; on April 6, at 9 a. m., one embryo was found.

Blood counts, on April 6, 9 a. m., were as follows:

Reds, 3,866,666; whites, 18,760. L., 10.66 per cent.; L. M., 5.66 per cent.; E., 12.33 per cent.; P. N., 69 per cent.; T., 3 per cent.; 200 counted.

April 17, noon. Reds, 4,700,000; whites, 22,000. L., 9.6 per cent.; L. M., 4 per cent.; E., 22.4 per cent.; P. N., 61.6 per cent.; T., 2.4 per cent.; 200 counted.

On April 18, beginning at 9 a. m., hourly counts of the number of embryos per c.c. and leucocytes per cm. (during day time) and differential white blood counts were made during the following twenty-four hours:

NUMBER OF EMBRYOS PER CC. OF BLOOD.

April 18, 9 a. m.	0	April 19, 1 a. m.	672
April 18, 10 a. m.	0	April 19, 2 a. m.	840

April 19, 6 a. m. L., 12.5 per cent.; L. M., 4 per cent.; E., 15 per cent.; P. N., 65.5 per cent.; T., 3 per cent.; 200 counted.

April 19, 7 a. m. Whites, 18,600. L., 13.5 per cent.; L. M., 3 per cent.; E., 17.5 per cent.; P. N., 63 per cent.; T., 3 per cent.; 200 counted.

April 19, 8 a. m. Whites, 22,000. L., 13 per cent.; L. M., 4 per cent.; E., 14 per cent.; P. N., 65 per cent.; T., 4 per cent.; 200 counted.

April 19, 9 a. m. Whites, 18,666. L., 12 per cent.; L. M., 4 per cent.; E., 16 per cent.; P. N., 64 per cent.; T., 3 per cent.; 200 counted.

April 27, 9 a. m. Reds, 5,200,000; whites, 23,000. L., 13 per cent.; L. M., 3 per cent.; E., D 14 A; P. N., 68 per cent.; T., 2 per cent.; 200 counted.

May 1, 10 a. m. Reds, 5,200,000; whites, 18,000. L., 16 per cent.; L. M., 4 per cent.; E., 18 per cent.; P. N., 60 per cent.; T., 2 per cent.; 200 counted.

May 6, 2 p. m. Reds, 5,160,000; whites, 20,000. L., 12 per cent.; L. M., 4 per cent.; E., 15 per cent.; P. N., 66 per cent.; T., 3 per cent.; 200 counted.

May 8, 8 a. m. Reds, 5,200,000; whites, 17,000. L., 13 per cent.; L. M., 4 per cent.; E., 14 per cent.; P. N., 66 per cent.; T., 3 per cent.; 200 counted.

CASE 3.—M. R.; male Filipino; age 56; native of Albay; well built. Physical examination negative excepting slight enlargement of the right spermatic cord, and small right hydrocele. Right testicle was normal in size and hard. Chills, fever and some headache had occurred at irregular intervals during the past year. Two embryos were found in specimens of blood taken on April 4, 1901, at 11 p. m.; in that on April 6, 9 a. m., two.

On April 18, reds numbered 3,620,000; whites, 8,000 per cm. Differential count: L., 14 per cent.; L. M., 4.5 per cent.; E., 15 per cent.; P. N., 64 per cent.; T., 2.5 per cent.

On April 23, beginning at 2 p. m., hourly counts of the embryos per c.c. and leucocytes per cm. (during day time) and differential counts of the leucocytes were made.

Number of embryos per c.c.:

April 23, 2 p. m., 84; 3 p. m., 0; 4 p. m., 0; 5 p. m., 84; 6 p. m., 84; 7 p. m., 504; 8 p. m., 588; 9 p. m., 1680; 10 p. m., 1596; 11 p. m., 1512; 12 p. m., 1428.

April 24, 1 a. m., 1008; 2 a. m., 1008; 3 a. m., 840; 4 a. m., 672; 5 a. m., 504; 6 a. m., 168; 7 a. m., 756; 8 a. m., 1092; 9 a. m., 336; 10 a. m., 588; 11 a. m., 336; 12 noon, 84; 1 p. m., 0; 2 p. m., 84.

May 6, 336.

May 8, 2 p. m., 0.

On April 23, 2 p. m. Red blood count, 3,552,000. Whites, 7600. L., 19 per cent.; L. M., 3.5 per cent.; E., 6.5 per cent.; P. N., 68 per cent.; T., 3 per cent.; 200 counted.

April 23, 3 p. m. Whites, 8000. L., 15 per cent.; L. M., 3.5 per cent.; E., 8 per cent.; P. N., 70.5 per cent.; T., 3 per cent.; 200 counted.

April 23, 4 p. m. Whites, 8000. L., 19.5 per cent.; L. M., 4.5 per cent.; E., 8 per cent.; P. N., 66 per cent.; T., 2 per cent.; 200 counted.

April 23, 5 p. m. Whites, 6666. L., 20 per cent.; L. M., 3 per cent.; E., 7.5 per cent.; P. N., 67 per cent.; T., 2.5 per cent.; 200 counted.

April 23, 6 p. m. Whites, 13,333. L., 20 per cent.; L. M., 4 per cent.; E., 7 per cent.; P. N., 66 per cent.; T., 3 per cent.; 200 counted.

April 23, 7 p. m. L., 20 per cent.; L. M., 3 per cent.; E., 7 per cent.; P. N., 68 per cent.; T., 2 per cent.; 200 counted.

April 23, 8 p. m. L., 16 per cent.; L. M., 4 per cent.; E., 6.5 per cent.; P. N., 70 per cent.; T., 3 per cent.; 200 counted.

April 23, 9 p. m. L., 23 per cent.; L. M., 3 per cent.; E., 6.5 per cent.; P. N., 64.5 per cent.; T., 3 per cent.; 200 counted.

April 23, 10 p. m. L., 18 per cent.; L. M., 4 per cent.; E., 7 per cent.; P. N., 67 per cent.; T., 4 per cent.; 150 counted.

April 23, 11 p. m. L., 22 per cent.; L. M., 4 per cent.; E., 7 per cent.; P. N., 64.5 per cent.; T., 2.5 per cent.; 300 counted.

April 23, 12 p. m. L., 21 per cent.; L. M., 3 per cent.; E., 6 per cent.; P. N., 65 per cent.; T., 2 per cent.; 150 counted.

April 24, 1 a. m. L., 22 per cent.; L. M., 3 per cent.; E., 8 per cent.; P. N., 65 per cent.; T., 2 per cent.; 150 counted.

April 24, 2 a. m. L., 22 per cent.; L. M., 3 per cent.; E., 3 per cent.; P. N., 65 per cent.; T., 3 per cent.; 200 counted.

April 24, 3 a. m. L., 22 per cent.; L. M., 3 per cent.; E., 6 per cent.; P. N., 67.5 per cent.; T., 1.5 per cent.; 200 counted.

April 24, 4 a. m. L., 19 per cent.; L. M., 3.5 per cent.; E., 8 per cent.; P. N., 67.5 per cent.; T., 2 per cent.; 200 counted.

April 24, 5 a. m. L., 18.5 per cent.; L. M., 4 per cent.; E., 14.5 per cent.; P. N., 61 per cent.; T., 2 per cent.; 200 counted.

May 8, 2 p. m. Reds, 3,500,000. Whites, 12,000. L., 20 per cent.; L. M., 6 per cent.; E., 12 per cent.; P. M., 60 per cent.; T., 2 per cent.; 200 counted.

CASE 4.—Blood examinations of Case 4 substantiate the findings of Cases 2 and 3, but add no new facts. No trichinae could be found in a portion of the biceps muscle.

The accompanying chart shows the periodicity of the eosinophilia. This periodicity depends on the periodicity of the embryos in the peripheral circulation as shown by Manson.⁵ He found the embryos clumped together in the large arteries and irregularly scattered through the capillaries during the daytime and in the peripheral circulation during the night. The blood vessels of the lungs seemed to be the favored hiding places during the daytime.

Recent work on trichinosis, ankylostomiasis and the present work⁶ on filariasis show that these parasites have a positive chemotaxis for eosinophiles and that wherever in the body the parasite may be located there eosinophiles will be found.

When the embryos are crowded into the capillaries a local positive chemotaxis for eosinophiles gradually attracts these cells from the general circulation. As the embryos reënter the peripheral circulation this local positive chemotaxis is removed, allowing the eosinophiles to reënter the general circulation. The movement of

the eosinophiles must be some hours later than that of the embryos.

DESCRIPTION OF CHART.

Each horizontal line represents 84 embryos and 1 percentum of eosinophiles. Each perpendicular line represents one hour of time. In the time indicated by A. P.—from 9 a. m. to 5 p. m.—no embryos were found; during these hours the eosinophilia in the peripheral circulation was greatest; from 5 p. m. to 11 p. m. the number of embryos per c.cm. of blood was increasing, while the eosinophilia was decreasing; from 11 p. m. to 8 a. m. the number of embryos was decreasing and the eosinophilia increasing.

Cases 2 and 3 were recently infected, while in 1 and 4 the duration of the disease could not be ascertained. Cases 1 and 4 did not have trichinosis, while 2 and 3 were not examined. All of the cases show a decided eosinophilia associated with filariasis. In the most recent case, Case 2, the highest eosinophilia was found. In cases of long standing eosinophilia has not been observed.

In the light of the above works it may be stated that during the early stages of filariasis a leucocytosis and eosinophilia are present; that the leucocytosis and eosinophilia are cyclic, following by a few hours the

periodicity of the embryos in the peripheral circulation, and that as the disease progresses the leucocytosis and eosinophilia gradually decrease to normal. As yet the duration of these phenomena have not been determined.

Why the Yellow Newspaper is Against the Medical Profession.—In his excellent address (*Colorado Medical Journal*, July, 1902) Dr. S. D. Van Meter states that in 1901 the four leading newspapers of Denver received about \$72,000 for advertisements from the illegal and advertising practitioners of the city. And yet Dr. Van Meter says that if any one of these papers would refuse such immoral and indecent advertisements, and would champion the cause of right and public welfare, there would be an instantaneous increase of circulation, as a result of professional influence, that would more than offset the loss of income from the criminal advertising. The problem, therefore, is for the profession and honorable-minded citizens, first, to unite their influence, and then to bring it to bear upon the conscienceless newspaper publisher. The condition of medical progress is thus demonstrated from another side to consist in organization. Let us organize!—*Amer. Med.*

THE ROLE OF THE TOXINS IN INFLAMMATORY PROCESSES.

The time has probably arrived when the pathologist should insist that the professional gaze shall no longer be directed to pathogenic bacteria as the sole agent in the production of inflammation. For many years we have known that infective alterations in the tissues are not always to be explained by the presence of bacteria, although it is also well established that the initial disturbance is very frequently due to microbial invasion. One of these numerous instances is found in migratory ophthalmia. This example is chosen because it well exemplifies the progress made in very recent times in the domain of bacteriology. The experiments of Harold Gifford, Deutschmann and others have clearly shown that the path of infection in "sympathetic" ophthalmia is along the vaginal canals (and other lymph spaces) of the optic nerve, from the injured and infected eye to the chiasma, thence, by way of the opposite nerve, to the "sympathizing" eye—but, in the great majority of instances where an examination of the uninjured eye was made, no bacteria whatever were discovered. The sympathizing eye was generally found to be "sterile." This fact was variously interpreted by those whose faith in the germ theory of disease was still unshaken. The microbes were destroyed, they said, before the examinations had been made, but after they had reached the second eye and, in some mysterious way, had accomplished their purpose of setting up in it destructive changes closely resembling those seen in the primary lesion. Other observers, feeling this negative evidence insufficient, fell back on the old hypothesis that furnished the early name to the disease, viz., that the irritation of the sympathetic (ciliary) nerves in the injured eye was sufficient to induce a similar form of inflammation in the fellow eye. Those who retained this belief and who, in confirmation of their contention, occasionally found alterations in the ciliary nerves of the sympathizing eye, failed to explain why migratory ophthalmia is rarely encountered except in penetrating wounds of the eye, and why it is particularly to be feared in infected wounds of the principal lymphatic area of the interior of the globe—the region of the ciliary body.

We are now well aware that the second eye is, in all likelihood, poisoned by the toxins excreted by pathogenic bacteria introduced into the "exciting" eye.

Doubtless the time is not far distant when chemical reagents (and not the microscope hitherto relied on) will not only demonstrate the presence of these alkaloidal poisons in the "sympathizing" eye, but will reveal the name of the bacterium or bacteria that originally furnished them. This probability, as well as other questions regarding the part played by toxins in the production of inflammation, has, relatively, been little discussed. Strange to say, also, among the numerous elaborate, exhaustive and original investigations in bacteriology comparatively little has been done for what might be called bacterial toxicology. A sufficient reason for this lies, perhaps, in the marked instability of the toxins, their complex composition, the ease with which they form new combinations and the obstacles that oppose their isolation or classification. With few exceptions we have no reliable chemical tests for them, and have mostly to rely on their biologic reactions and relations.

No better exposition of the part played by toxins in inflammatory lesions has so far been published than the essay to which was quite lately awarded the Boylston prize.¹ This was prepared by Dr. Robert L. Randolph, who took as his experimental territory the rabbit's eye, using on it the following bacteria and their toxins: the *Gonococcus*, *Koch-Weeks bacillus*, *Bacillus diphtheriae*, *Staphylococcus aureus*, *Pneumococcus*, *Micrococcus epidermidis albus*, *Streptococcus pyogenes*, *Bacillus coli communis* and the *Bacillus xerosis*. Randolph reminds us that experiments with the three bacteria first mentioned, as well as with the Morax-Axenfeld diplobacillus, are beset with many difficulties because they produce little or no reaction in the conjunctiva of animals, inasmuch as that membrane does not furnish a proper soil for their growth.

The work is divided into four parts; first, the study of the effect produced by toxins when they are instilled into the conjunctival sac; second, the results following their injection beneath and into the tissues of the conjunctiva; third, the effect produced by their introduction into the anterior chamber, and fourth, as an adjunct to or as a complementary study of the foregoing, the bacteriology of the normal conjunctiva of the rabbit, based on an examination of forty-seven cases. Forty experiments, recorded under the first heading, demonstrate that mere contact of bacterial toxins with the normal conjunctiva of the rabbit produces no local inflammation or other injurious effect on that animal. Randolph justly claims that his experiments are the first to demonstrate that, unlike alkaloidal and many other poisons, these chemically undefined toxins, excreted by bacterial cells, in common with similar poisons produced by certain cells of the higher order of plants, notably ricin and abrin, and of some animals, snake venom for example, are, as a rule, incapable of absorption by

1. Am. Jour. Med. Sci., November; See THE JOURNAL, Nov. 22, p. 1349, Abstract 60.

intact mucous surfaces. They demonstrate how very important it is to preserve the epithelial integrity of absorbing membranes against those poisonous agents that lie in wait to invade the organs they cover and protect. He does not attempt to prove or disprove Ehrlich's "side-chain" theory of infection, but he does assert that the primary and essential damage to the rabbit's conjunctiva, in the presence of pathogenic bacteria and toxins, is produced by the latter. If the bacteria are secondarily active during the infective process it is because the soil has already been prepared for them by the changes first wrought in the cells and tissues by the toxins. These contentions are further fortified by the numerous experiments included under sections 2 and 3. Randolph is able to show that bacterial filtrates from both old and young cultures contain irritative poisons that promptly set up local inflammatory changes when injected into the substance of the conjunctival mucous membrane. This is especially true of the toxins secreted by the gonococcus, the colon bacillus, the diphtheria bacillus and by all the pyogenic cocci. On the other hand, control injections of the uninoculated culture media, in larger doses, produced no effect.

It was not surprising to find, after the results obtained by intraconjunctival injection of the toxins, that unequivocal reactions follow their introduction into the anterior chamber of the eye. Filtrates were employed in these experiments, not only from bacterial cultures already known to produce powerful toxins, but also from some others not before shown, by the biologic tests, to secrete active, soluble toxins. In every instance Randolph was able to demonstrate that the intraocular (especially the intraconjunctival) reaction is more delicate than the usual antiserum or other biologic test in determining the presence or infective quality of the various toxins. That the toxins concerned are not simply the "bacterio-proteins" of Buchner, derived from macerated and degenerated cells, is proved by the use of young cultures only. The conjunctival sac of the rabbit's eye, as in the human organ, was found to harbor numerous bacteria, pathogenic and harmless, and there is reason to believe that both in man and in the lower animals these vary from time to time as to number and pathogenic quality.

The "practical" conclusion to be drawn from this work has long been known to us; we are comparatively safe from microbic invasion as long as the protective epithelium that covers our bodies and lines our canals remains intact. For example, mere rubbing of an eye into which a cinder or other foreign body has flown may result in its destruction from spreading ulcer of the cornea due to infection of the abraded spot from otherwise harmless colonies of the pneumococcus. May not this statement also hold good of bacteria in the pulmonary, intestinal and genito-urinary tracts? On the other hand, the precise character of the infective injury and our knowledge of the agents that produce it are more

clearly defined than ever before from the painstaking investigations of Randolph.

THE PATHOLOGY OF CONVULSIVE DISORDERS.

The careful and systematic study of any one of the chronic convulsive disorders is certain to throw much light on all. The problem of discovering their nature and pathology must rest largely in the future on the correlation of such studies. The gradual change of the location of the lesion of convulsive diseases from the muscle, peripheral nerve, medulla and basal ganglia to that of the cerebral cortex has been brought about largely through detailed studies on isolated cases.

It is of particular interest to note that much of the newer work on the pathology of many so-called functional disorders, such as epilepsy, chorea, convulsive ties, myoclonies and the like, brings them more nearly to a common pathology and pathogenesis; that is, to an organic basis with a definite cortical lesion, degenerative in type. This has been well shown in the work of Clark and Prout¹ on status epilepticus, and still more recently on the association disease myoclonus-epilepsy.² The article consists of a careful review of the causes, symptoms, prognosis, pathology and treatment of the disease with the additional report of three new cases which, with one previously reported by Clark, constitutes the only ones on record at present in the English language. The authors summarize the gross pathologic lesions in the associated disease which have been found by previous workers to be slight meningitis and accumulation of cell elements about the vessels and ganglion cells, with some increase of the interstitial tissue products, often seen in degenerative processes of the brain and meninges—findings that throw but little light on the real pathogenesis of the disease. In one case of their own, examined under what are considered at present ideal conditions, the authors report definite and marked histopathologic changes.

"The characteristic lesion of epilepsy in the second or so-called sensory cell was found. This consisted in a destruction of the intranuclear network and its replacement by a granular substance. As a consequence of this change in the cell body abstraction of the nucleolus from the cell occurred easily and frequently in cutting the section. In addition to the epilepsy lesion which was found and conclusively proven to be present in various forms and conditions of the disease, identical cell destruction was found in the large pyramids of the third cortical layer. The large chromatic granules of the Betz or motor cells of the paracentral lobule were quite as much involved as the chromatic substance in the cells of the smaller type. Chromatolysis was extreme over the entire cortex. The general distribution of the lesions was striking; chromatolysis, absence of the nuclear membrane and the presence of granular and swollen nuclei, in every portion of the cortex examined.

1. Proceedings of the N. Y. Neurological Society, October, 1900.
2. American Journal of Insanity, vol. lxx, No. 1.

It is essential to recognize that in these findings we have the lesion of epilepsy of the second layer cells, plus a maximum intensity of the same form of cell death in the large pyramidal cells of the third layer. Presumably the latter changes underlie the myoclonic spasm. The two diseases have a common soil of degeneracy, which is expressed in an organic cellular anomaly of the second and third layers of the cortex. This anomaly, constituting the predisposition, manifests itself at the supererogation of an immediate excitant in epilepsy and myoclonus. However, additional evidence of the constancy of the lesion supposed to underlie the myoclonus is very important and necessary. If the primary lesion is in the cerebral cortex and involves the autonomy and life of sensory and motor cells in the same death process, we must infer that the excitant is probably a general toxic or autotoxic agent, acting in a uniform manner on these particular cells. As before pointed out, the soil for the implantation of the association disease is so remarkably degenerative that the intoxication may be slight and transient only. It will be, therefore, doubly difficult to detect."

In a final conclusion the authors say "that the lesion of myoclonus epilepsy appears to be in the cerebral cortex involving the nucleus and the intranuclear network of cells of both sensory and motor types. Its pathogenesis appears to be an intoxication or auto-intoxication of these cortical elements, probably brought about by a faulty chemotaxis of these same cells because of an inherent organic anomaly. While each condition maintains its separate morbid entity the two are closely allied, and indeed are often found as indissolubly associated clinically and pathologically as are the motor and sensory functions of the cells they involve."

For years Chaslin, Féré, Marinesco and Binswanger have urged gliosis as the essential lesion of the epilepsies and, in point of fact, for all chronic convulsive disorders. The glial changes show themselves as a sclerosis of different cortical areas, especially of the cornu ammonis. But it now appears that such lesions are a result and not the initial or progressive part of the cortical lesion. From a pathologic standpoint it has long since been recognized that primary interstitial change in any tissue is steadily growing rarer. Primary connective tissue changes are almost unknown in the pathology of the nervous system. It does not seem, therefore, illogical that the initial parenchymatous change in the epilepsies should be insisted on by Clark and Prout. As these writers contend, it is quite possible that the earliest lesion of the cortex in epilepsy and allied convulsive disorders is one of destruction of the cell elements brought about by autotoxic agents, the ultimate result of which is a progressive glial replacement and overgrowth.

TREATMENT OF INOPERABLE MALIGNANT DISEASE.

The results of operative treatment of malignant disease, even under the most favorable conditions, are on

the whole so discouraging that it is not surprising that cases which are clearly thought to be inoperable are frequently neglected. The large number of patients who fall a prey to quacks because of such neglect makes it the imperative duty of a practitioner to try every known means of alleviation, if not of cure, for these distressing cases. Means which have been employed with more or less success are numerous. Coley's serum is among the best known of such curative agents, and has undoubtedly cured a number of cases of spindle-celled sarcoma. It has not proved of any value in the treatment of carcinoma or of most other forms of sarcoma, and like other means of this kind should not be employed except in inoperable cases. Oöphorectomy in cases of carcinoma of the breast, as suggested by Beatson of Glasgow, has also proved a successful means of treating a small number of cases. The proportion of cases influenced by such treatment is very small, however, and it can not be relied on either as curative or palliative in any given case.

The latest addition to our therapeutic resources in such cases is the *x*-ray treatment. A discussion¹ on the use of the *x*-ray took place at the last meeting of the British Medical Association. Mr. Thomas Bryant of London reported two cases of recurrent carcinoma breast in which the disease was apparently arrested by the use of the *x*-rays, as well as some cases of rect carcinoma which were benefited. Several others who took part in the discussion also reported favorable results from the use of the *x*-rays. The successes of several workers with the *x*-ray in this country are well known. The favorable results from all of these methods have been far too frequent to be due to chance, spontaneous cure, or errors in diagnosis, although the cures are so comparatively few in number that one would not be justified in advising any of these methods in truly operable cases. We say this in spite of the encouraging outlook in the use of the *x*-ray. Beatson spoke favorably of the use of thyroid feeding in connection with oöphorectomy, and Boyd has reported 17 cases in which the course of the disease was favorably influenced when this method was employed.

Among other measures, Adamkiewicz has used an aqueous solution of neurin citrate, which he calls cancroin, and reports² 6 cases which appeared to have been cured by this method. The results of cancroin treatment in the hands of others have not proved very satisfactory. Two years ago Vlaieff introduced a serum which he obtained by inoculating geese with cultures of blastomycetes derived from human carcinoma. The injections caused no risk to life, and he reported some cures from its use, but the investigation committee of Harvard Medical School reported negative results in both animal inoculations and cultural experiments with human carcinoma.

1. British Medical Journal, 1902, vol. II, pp. 1293-1307.
2. Berliner Klin. Woch., No. 24, 1902. See also THE JOURNAL, Aug. 16, 1902, p. 405, 491.

Besides curative means, much can be done with palliative measures in these cases. The relief of foul-smelling discharge by curetting or the use of the actual cautery and tamponing is often very great. Czerny even reported to the German Surgical Congress, 1900, a few cases which had been pronounced inoperable, but which were cured by excision or curettement and the use of 30 per cent. zinc chlorid solution. As a palliative measure the ligation of a main artery may be considered. Occasionally so much shrinkage of the growth occurs after ligation that radical operation is possible and hemorrhage can at least be prevented in this way. Formalin, arsenic pastes, iodid of potassium, injection of alcohol, electric treatment and many other measures have been used with more or less success and have their advocates. Although such means are not likely to give very brilliant results, there seems to be no reasonable objection to trying them, particularly in cases in which patients have heard of their value and desire to try them.

With few exceptions all attempts to cure malignant diseases by means other than early and free operation have hitherto proved almost invariably futile, but we believe that inoperable cases can be handled more successfully as regards the relief or possible cure of the patient by regular practitioners of medicine than by quacks. Those who are persevering in the treatment of such cases will undoubtedly be occasionally rewarded by obtaining a cure. Such cases should certainly not be allowed to fall into the hands of quacks, who most frequently extort exorbitant sums of money and only add to the sufferings of the patient. The active investigations which are being made in so many different countries as to the cause and nature of carcinoma seem more likely to lead to means of prevention and cure in such cases than any treatment which is at present known.

OSTEOPATHIC LAW.

A Missouri judge has recently given a medicolegal decision that it seems to us will hardly stand the revision of the higher courts. It is in effect that in cases of malpractice the testimony only of physicians of the same alleged school of practice as the medical party in the case can be accepted. The case in court was one against one of the osteopathic Stills of Kirksville, Mo., and the judge ruled that the study of one school of medicine did not qualify a practitioner to give an intelligent opinion on the work of one of another school. Osteopathy is thus impregnably fortified by this Missouri decision as long as it stands, a fact that is worth advertising for the benefit of those who may propose to submit themselves to osteopathic massage. If they do not get satisfaction from the operation or treatment they need not expect to get any more from this judge or other Missouri judges who, like him, stand up for the institutions of their state. Another osteopathic decision is reported as handed down by a Colorado judge, who decides that the osteopaths have a right to advertise

themselves as doctors and to practice independent of any restrictions by the state law. This, we understand, is also a lower court decision, and may be revised. If not, a little more legislation is required in Colorado.

THE USELESS CORONER.

The movement to abolish the office of coroner in New York seems to be one that ought to receive the general support of the profession. The office is an antiquated one that has survived its usefulness and really only exists as a political plum; its judicial functions could be better exercised by other officials provided for by law, and its medical duties would be much more satisfactorily attended to by medical men without interference by laymen or subordination to politicians. The name of the office is itself an anomaly in a republican government, and it is a little remarkable that it has been so long endured, when its imperfections were a matter of satire and ridicule even in Shakespeare's day. The experience of Massachusetts has shown the needlessness of the office, and it is the more surprising that the common sense of other commonwealths has not before this induced them to follow her example in abolishing it. If it is, as is stated, not a constitutional office in New York, its abolition ought to be an easy matter; some other states are probably not so well off, and will have to endure this expensive relic of monarchical barbarism the longer. The action in New York, however, will be a stimulus to reform in this matter elsewhere.

MUSIC AND SCIENCE IN TUBERCULOSIS.

Down in Missouri they have novel methods of prophylaxis. Music of a certain kind has been found to drive away its hearers, but the use of this means to expel the bacilli of tuberculosis is, to say the least, unique. In Holy Writ we are told that devils were cast out by adjurations; and various savage tribes use tom-toms and other barbaric musical instruments to exorcise demons and thereby cure disease; it remains for Missouri, however, to combat dread tuberculosis by a judicious combination of useful information and music. At the first public meeting of the Missouri State Society for the Prevention of Tuberculosis in Kansas City, December 2, the program appropriately began with Mendelssohn's Wedding March, followed by an address on "The Necessity of the Movement." Relief was then afforded by two songs, "I Love Thee" and "The Violet." "The Necessity of Registration" was next discussed, after which a quartette sang the "Spring Song" and "Oh, Hush, Thee, My Baby." After an article on "The Danger in Our Schools from Consumption" a Chopin polonaise was played, supposedly to relieve the tension. The next address on "Contagiousness of Consumption" was gruesomely followed by a song "Till Death." And so the program went on with sandwiches of science and art. The report is incomplete, as it does not detail the effect of the alternate mental strain and relaxation on the audience. It would be interesting to contemplate the effect if such an innovation were made to relieve the strenuousness of the programs of some of our solid, not to say stolid, medical society meetings.

VALUE OF VIVISECTION TO BRAIN SURGERY.

Dr. Keen sets a commendable example by publishing direct and striking evidence of the value to man of animal experimentation. Senator Gallinger holds a medical degree (Homeopathic), and probably this is why he has been selected to represent the antivivisection cult in the Senate. To him Dr. Keen addressed the letter which is published elsewhere,¹ describing a case cured by an operation, the success of which was made possible through knowledge obtained from experimentation on animals. It is only one concrete example of what is occurring constantly wherever medicine is practiced. Midshipman Aikin recently sustained at Annapolis an injury to the head while playing football. No fracture of the skull could be found, but there was visible a slight bruise at the outer end of the left eyebrow. Soon after the accident he became unconscious, but later slightly rallied and complained of bad frontal headache. Soon after this he began to develop convulsions, and within six and one-half hours had clonic spasms of the right arm twenty-four times—a bad outlook for the patient. The physicians and surgeons of this country could in a year's time furnish Senator Gallinger with hundreds, if not thousands, of cases as conclusive as this, in which lives have been saved as a result of knowledge obtained from vivisection. In order that public opinion may be educated in this regard, it is important that some of the constantly occurring cases should be thus given to the public.

IDENTIFICATION BY PALM AND SOLE PRINTS.

A number of observers have recently called attention to the fact that the finger prints of different individuals are perfectly characteristic and that they may be used as a means of identification. Francis Galton has studied the subject most elaborately, and his books on "Finger Prints" and "The Decipherment of Blurred and Indistinct Finger Prints" are well known to those interested in such matters. Prof. H. H. Wilder² of Smith College again calls attention to this subject and gives some interesting data as regards the prints from the sole of the foot as well as from the palm of the hand. He mentions recent interesting studies made by Colonel Mallory of the United States Bureau of American Ethnology, who has found scratchings on the slaty rocks near Lake Kejienkoojic in Nova Scotia, which are supposed to be the work of aboriginal Micmac Indians and date back to pre-Columbian times. These scratched drawings of the lines of the palms and soles show a remarkable degree of detail which must have been the result of unusually careful observations. The scratchings on the tip of the fingers have also been interpreted as either indicating walking pads or it has been suggested that the reason that they have been used is the idea of some primitive people that originally each part of the body terminated in an organ of sense, particularly an eye. From this was supposed to result the fancied resemblance between the shape of the pattern and the eye. One of these explanations seems more likely than that the aborigines were really careful students of palmar and plantar prints. A study of the prints from the

sole of the foot leads Wilder to believe that the sole prints are as characteristic in their patterns as are the prints of the palms, and he suggests that in the majority of cases even a cursory study of the main lines and areas of prints of the soles and palms would be sufficient to identify an individual. This might be made use of, he believes, as a means of identification, which would be a very practical extension of the Galtonian system. Such a system of identification by prints would be useful in the numerous cases in which identification of the body living or dead becomes a matter of importance for whatever reason. There are countless cases of this kind in which identification is a matter of doubt and uncertainty and great expense is involved. The system, Wilder believes, would prove a better and surer guide than the usual rogues' gallery photograph or even a set of Bertillon measurements. It would be available in many cases in which from accidents of various sorts bodies are mutilated so as to render recognition very difficult.

Medical News.

DISTRICT OF COLUMBIA.

Morbidity and Mortality of the District.—The cases of typhoid fever have now fallen below 300. During the week ended November 22, five deaths were reported from typhoid fever. The total mortality for the week showed a decrease of 20 per cent. as compared with the preceding week. The deaths for the week numbered 91, equivalent to an annual rate of 16.2 per 1000.

Resolutions Regarding Dr. Reed.—The faculty of the Columbian University has passed resolutions regarding the death of Dr. Walter Reed, U. S. Army, professor of bacteriology and pathology in the medical school of that institution.—At a meeting of the student medical officers, U. S. Army, class of 1902-1903, November 26, resolutions were adopted expressing the great sorrow of the members of the class for the sudden and untimely death of their beloved professor and associate, Major Walter Reed, surgeon, U. S. Army.

Change in Emergency Hospital Rules.—Members of the board of directors of the Emergency Hospital accepted an interpretation of the rules of the institution at a meeting held recently, which will work a marked change in the administration of the hospital. Hereafter the executive officer of the institution will not have authority to discharge the resident physician or either of the two assistant resident physicians. The new interpretation of the rules provides that the entire board of directors must act in charges preferred against physicians and take action leading to their dismissal.

ILLINOIS.

Coroner's Cases in November.—Of the 229 cases passed on by the coroner in November, 36 were suicides; 31 deaths were due to railway accidents; 26 to falls; 16 to alcoholism, and 13 to burns.

Isolation Hospital at Parental School.—An isolation hospital for the temporary shelter of pupils afflicted with contagious diseases will be built at the parental school at a cost of \$3000, an appropriation for this purpose having been made, December 5, by the buildings and grounds committee of the Board of Education.

Decision Against Dr. Neely.—On December 3, Judge Dunne directed that the temporary injunction issued in the case brought by Adolph Ender to restrain the president of the county board and the county clerk from signing warrants for the payment of salaries to Medical Director John R. Neely be made permanent. He declared the Cook County Civil Service Commission should have made the examination of applicants for this position a promotional one instead of original. He further declared that the evidence showed that a promotional examination could have been held for the office of medical director, as there were several physicians in the same class with Dr. Neely. An appeal from the ruling will be taken to the upper courts.

1. See page 1537.

2. Popular Science Monthly, November, 1902.

Chicago.

Alleged Licenseless Practitioner.—Mrs. Mary L. Lambert was arraigned, December 1, on the charge of practicing medicine without a license. After the preliminary hearing, the case was continued by agreement.

Extension of Presbyterian Hospital.—The Presbyterian Hospital has bought two residences on Ashland Avenue and Congress Street, for \$40,000. They will be remodeled immediately, and will be opened, January 1, as a home for nurses connected with the hospital.

Personal.—Dr. Albert H. Hoy and family have returned to Chicago, after an absence of eighteen months abroad.—Dr. Otto T. Freer has opened an office in the Venetian Building.—Dr. James B. Herrick has been appointed to the department of internal medicine, and Dr. John E. Rhodes to the department of laryngology in St. Mary's of Nazareth Hospital.

The Week's Deaths.—The total deaths—528—last week are 80 in excess of those of the previous week and the indications now are that the total deaths for the year will be fully 1600 more than the number for 1901. This will give an annual death rate of about 14.30 per 1000 of population for 1902, as compared with 13.88 for 1901—an increase of 3 per cent. The diseases chiefly threatening the public health at the present time are pneumonia and influenza. This latter disease, although prevalent since the early fall, has thus far been of a mild type, but there are indications of a growing virulence of the germ during the past fortnight.

No Insusceptibility to Vaccination.—The chief medical inspector, Dr. Spaulding, in the health board's bulletin, says:

Several times recently attention has been called to a false impression concerning insusceptibility to vaccination held by many persons and even by some medical men. They argue that because a child has had six or seven attempts at vaccination, without its "taking" that the child is insusceptible to the operation, and have asked permission for such child to enter school without the required certificate. They have even come with a letter from the family physician, stating that a given child is insusceptible. It should be clearly understood that no one is insusceptible to vaccinia or vaccination. One successful vaccination can be secured in every person; to this there is no exception. Repeat the attempt until it does "take."

A striking and hideous illustration of the evils of teaching insusceptibility to vaccination was furnished during the week in the neighboring town of Hammond, in which a cashier in the bank was stricken with smallpox in its worst form. He died on the seventh day of the attack with hemorrhagic smallpox. He had had four attempts at vaccination, and because it did not "take" was told he was insusceptible to vaccination—a bit of medical advice which cost him his life at the age of 33—an utterly needless loss of a life useful to the community and of priceless value to his family.

IOWA.

Alleged Illegal Practitioners.—Bruce Gardner, Davenport; A. E. Porter, Fort Madison, and Dr. Rae, Estherville, have been arrested on the charge of practicing medicine without a license.

Bill of Sale Filed.—A bill of sale was filed, December 1, conveying the property of the *Iowa Medical Journal* from E. G. Ragsdale to the Dorr Investment Company, Des Moines, for a consideration of \$2000.

In Memoriam.—In memory of Mrs. Henrietta W. Dows, St. Luke's Hospital, Cedar Rapids, is to be given a complete surgical department, consisting of three rooms and a corridor, thoroughly equipped, by Hon. S. L. Dows and children.

Personal.—Dr. Grant J. Ross, Sioux City, has been appointed a member of the Woodbury County Board of Insanity Commissioners, vice Dr. Van Buren Knott.—Dr. C. D. Harlan, Clarinda, a member of the staff at the State Hospital, has accepted an instructorship in surgery in the State University, Iowa City.—Dr. William S. Lessenger, Mount Pleasant, has been elected vice-president of the Southeastern Iowa Medical Association.—The office of Dr. George Inglis, Monticello, was destroyed by fire, November 30.

MARYLAND.

Baltimore.

Personal.—Dr. Martin B. Billingslea is very ill with a carbuncle on his neck.—Dr. Peter H. Reiche is recovering from an attack of pneumonia.

Detention House Leased.—The health department has leased a detention house for smallpox suspects or those who have been in contact with smallpox cases. Genuine smallpox cases found in the city will, however, be sent at once to quarantine.

The Fight Against Smallpox.—The health board has expended \$5700 of the \$10,000 appropriated to its use at the beginning of the year for the purpose of combating smallpox. The

success in preventing its lodgment here to any considerable extent is most praiseworthy.

In Memory of Professor Friedenwald.—A memorial meeting in honor of the late Prof. Aaron Friedenwald was held at the College of Physicians and Surgeons, December 2. Addresses were delivered by Drs. William Simon and John Ruhrah. Appropriate resolutions were offered by Dr. George J. Preston of the faculty.

Death and Disease.—The health department reports measles still increasing; 247 cases were reported last week, although the type is mild. There were 186 deaths, a death rate of 17.23 per 1000 per annum. From pneumonia 20 died; from bronchopneumonia, 7; from bronchitis, 6; from typhoid fever, 3; from measles, 2; from consumption, 7, and from diphtheria, 1.

Magness Forfeits Bond.—News has been received from West Virginia that Dr. Thomas H. Magness has forfeited the bond of \$500 given by his attorney to secure his appearance to answer the charge of taking the state medical examination in the name of David R. Shepler and swearing falsely to his identity. It is said that the warrant for Dr. Magness was lost or stolen, and that the State Board of Health of West Virginia will institute an inquiry into the case and prosecute the guilty party.

Lorenz in Baltimore.—Dr. Adolf Lorenz arrived, December 6, and became the guest of Dr. R. Tunstall Taylor, surgeon-in-charge of the Hospital for Crippled and Deformed Children. He delivered a lecture in the anatomical hall of the University of Maryland, and demonstrated his method of reducing congenital hip dislocation on a little girl. On Sunday he visited the Hospital for Crippled and Deformed Children, and on Monday visited the Johns Hopkins Hospital and left for Philadelphia the same afternoon.

Medical Colleges.—According to the new register of the Johns Hopkins University, just out, there are 69 professors and instructors in the medical department; 258 medical students, and 72 physicians attending special courses. The number of matriculates in the University of Maryland School of Medicine this year is 300. The Baltimore Medical College has about 425 students. The College of Physicians and Surgeons about 325, and the Maryland Medical about 200. The Woman's Medical College has a very small class.

NEW YORK.

Smallpox in Rochester.—On November 29 there were 122 smallpox patients in Hope Hospital, Rochester.

Consumption Among Convicts.—Superintendent of Prisons Collins will report to the next legislature surprising results of the scientific care of consumptive criminals. The large death rate in the prisons previous to the past few years was due mainly to consumption, and to minimize, if possible, this condition, Superintendent Collins has had all consumptive prisoners sent to the state prison at Dannemora, in the Adirondacks, one of the best places in the world for the treatment of the disease. Here the consumptives were subjected to a special treatment in the prison hospital, with the result of an estimated decrease in the death rate from this cause of 71 per cent. in the past five years compared with the five preceding years.

The Care of the Insane.—Important conferences under the direction of the State Commission in Lunacy have been held during the present week in the pathologic institute on Ward's Island, New York. The newly-chosen director, Dr. Adolf Meyer, has delivered a series of lectures on the scientific treatment of the insane, which have been attended by all the superintendents of the state hospitals and other interested scientists in this and other states. President Peterson of the commission has united with Director Meyer in urging that still greater attention be paid to the acute insane admitted to the state hospitals, and the commission believes that a fresh impetus to the study of causation as well as treatment will result from the conferences.

New York City.

Acid Fumes in Cars.—For a long time the fumes from the storage batteries in certain electric cars have caused discomfort and ill health among passengers. The board of health has taken a firm stand against the nuisance, and the car company has yielded to the pressure by fitting up several cars with a device, suggested by Dr. Hudson, for carrying the acid fumes some distance above the roof of the car. This arrangement is said to operate very well.

Personal.—Dr. Otto H. Schultze has been appointed coroner's physician, vice Dr. Hamilton Williams, resigned.—Dr. Philip F. O'Hanlon has been confirmed as coroner's physician.

—Dr. Jesse P. Duryea, who has been general medical superintendent of the King's County Hospital and Almshouse since 1898, resigned, December 10. At a farewell reception to Dr. Duryea, December 3, he was presented by the employes of the hospital with a diamond ring.

New Plans of Health Department.—One of the most important of the new plans involves the establishment of an East Side branch of the health department that, the commissioner promises, is to be in working order by next March. It will be open day and night, to attend to vaccination, and will have a complaint bureau and a place for the issuance of certificates to relatives and friends to visit patients in the public hospitals, thus sparing residents of the district the necessity of making the long trip to the head office.

Medical Supervision of the Isthmian Canal.—The New York Academy of Medicine, in view of the demonstrated ability of proper sanitary measures to control malaria and yellow fever, has adopted a resolution, declaring that the amplest powers should be given to the medical officer in charge of the sanitation of this canal, calling the attention of the President of the United States to this fact, and asking that the President, as the one authorized to appoint the commission, see to it that the medical officer be made a member of this commission.

Alleged Death from Tetanus Following Vaccination.—On November 30 a boy living in the borough of the Bronx died from what is reported to have been tetanus. The parents allege that the boy was vaccinated, November 19, by one of the physicians of the health department, and that within twenty-four hours the boy began to complain of muscular pains. If this statement is correct, of course the vaccination can not be held responsible. It is also reported that at the same time a servant in the family was vaccinated. The case is being investigated by the board of health.

Typhoid Prophylaxis.—A committee has been appointed by the New York German Medical Society, consisting of Drs. Abraham Jacobi, Isaac Adler, George W. Jacoby, Richard Stein, Leonard Weber and Fritz Schwyzer to make suggestions regarding the prophylaxis of typhoid fever. After enumerating, in a letter to the mayor, board of health and aqueduct commissioners, the ravages of the disease in New York, the committee calls attention to the following important suggestions: Care in supplying good drinking water; enlightening the public; bacteriologic control of ice and oysters, and supervision of public closets.

Foot and Mouth Disease.—The health department of New York City has issued the following order: "All cars bringing cattle from New England states or from any part of New York State shall be accompanied by a sworn certificate stating that the car has been properly disinfected. On the absence of such certificate or on the declaration of this department that it has reason to believe that such disinfection has not been properly carried out, it shall be within the discretion of this department to order that cattle conveyed in such cars shall not be permitted to enter the stockyards of this city, but shall be ordered at once to a slaughter-house for immediate slaughter."

Buffalo.

Personal.—Health Commissioner Greene and City Bacteriologist William G. Bissell are attending the meeting of the American Public Health Association at New Orleans.—Dr. Jacob M. Krause has returned from Denver.

Exposure of an Impostor.—The *Buffalo Review*, a morning daily paper, deserves the appreciative thanks of the laity and medical profession of Buffalo for its exposure of an individual calling himself "Antonius the Boy Wonder," who practices magnetic healing and absent treatment on the poor and unwary. This journal states that Antonius is a faker, and many instances are given of his deception of poor cripples and the methods he employs of obtaining money from those least able to pay. This individual has been driven out of many cities, but because of the inactivity of the district attorney's office he has been allowed to remain in Buffalo.

PENNSYLVANIA.

Personal.—Dr. James V. Harsha, acting city physician of McKeesport, has resigned, and Dr. Frank John was elected in his stead.

Typhoid at Monessen.—An epidemic of typhoid fever prevails at Monessen. The cause is supposed to be contaminated well water.

Hospitals for Epileptics and Criminal Insane.—The State Board of Charities has decided to ask the state legislature for appropriations for the erection of a hospital for epilep-

tics and a separate institution for the criminal insane now confined in the state penitentiaries.

Urges Extension of Sewer System.—At the monthly meeting of the Reading Medical Association resolutions were adopted recommending that the city authorities take such necessary steps to extend the house sewerage system that all parts of the city may be included.

Philadelphia.

The University Day Oration.—Dr. S. Weir Mitchell has accepted an invitation from the board of trustees of the University of Pennsylvania to deliver the University Day Oration at the yearly commemoration of Washington's birthday.

Clinic for Children.—A clinic for children, including a nursery for motherless infants, has been established at the Jewish Maternity Hospital. Dr. I. Valentine Levi is in charge of the department, and Dr. Eleanor C. Jones is consulting pediatricist to the new department.

Illness and Death.—For the week ended December 6, 129 new cases of typhoid fever were reported, with 8 deaths. Six new cases of smallpox were reported, with one death. There were 450 deaths from all causes, a slight excess over the number for the corresponding week of 1901. There are said to be about 1200 patients at present under treatment for typhoid fever.

Abolition of Board of Charities and Correction.—Dr. John V. Shoemaker, president of the board of charities and correction, will, in his next annual report to the mayor, recommend abolishment of the board, and that the charities be placed under a commissioner and the house of correction in the department of public safety. The recommendation is one result of a visit made by the board to the public institutions of New York. The departments of charities and corrections in the latter city are presided over by commissioners who give their whole time to the work and are salaried officers. The inmates are also required to work. Neither of these conditions prevails in Philadelphia.

GENERAL.

Cholera is estimated to have cost 126,000 lives in the Philippines out of 208,000 cases thus far.

Southern Pacific Hospital Car.—This road is to have a car completely furnished as a hospital on wheels, with headquarters at Houston, Tex. The equipment includes an operating room.

Will Call Plague Conference.—Surgeon-General Wyman of the U. S. P. H. and M.-H. Service is reported to have said he would soon call the convention of all state boards of health that several of them have asked for.

"Dixie" To Be Hospital.—The Navy Department has approved the remodeling of the *Dixie* into a hospital ship. She will be only one of her kind. The complete overhauling and refitting will cost nearly a quarter of a million dollars.

Hawaiian Lepers Captured.—Three lepers, who have lived in the mountains of Hawaii and subsisted on the results of depredations, have at last been captured. They had all approaches under observation and were warned by friendly natives whenever attempts were made to find them. They were captured by a ruse. It is reported that two others are hidden in the same locality.

Many Deaths on Lakes.—The season of 1902 records 140 deaths on the great lakes, an increase over all previous years; 53 sailors went down with their ships, 47 men fell overboard and were drowned, and 15 lost their lives in collisions. Lake Erie was the grave of 59; Superior, 40; Michigan, 14; Huron, 22; Ontario, 54; the Detroit and St. Croix rivers, 10. The total loss of life on the lakes for each of the past seven years is as follows: 1896, 66 deaths; 1897, 88; 1898, 95; 1899, 100; 1900, 110; 1901, 132; 1902, 140.

Many Hawaiian Licenses Void.—Because of errors in office by former Treasurer W. H. Wright, twenty-nine physicians of Hawaii, sixteen of them Japanese, must pass new examinations. The chief error was in allowing a board of examiners to hold office for three years instead of two, as the law provides. During the unlawful period the board of medical examiners was out of harmony with the board of health. One disputed point was the admission of Japanese to practice and the requiring them to be examined in English. As the board of health favored a more rigid examination and was overruled by the examiners and the treasurer, the new examinations are expected to be more severe, and several Japanese have applied for an injunction against the loss of their present licenses.

Gibbs Memorial Prize.—The New York Academy of Medicine will award \$1000 to the author of the best essay on "The Etiology, Pathology and Treatment of the Diseases of the Kidney," presented by Oct. 1, 1904. Essays must be in English, typewritten, designated by a *nom de plume*, accompanied by a sealed envelope bearing the same *nom de plume* and containing the name and address of the author. No envelope will be opened except that of the successful author. There will be no award if no essay shall be deemed worthy. Unsuccessful essays will be returned if claimed within six months. An essay must show originality to obtain the prize. Members of the regular medical profession of the United States may compete. The original of the successful essay shall be the property of the academy, and will be published in its transactions. Essays should be sent to the Committee of the Trustees of the New York Academy of Medicine on the Edward N. Gibbs Memorial Prize, 17 West 43d Street.

CANADA.

The Royal Victoria Hospital, Montreal, reports for the month ending November 30: Patients admitted during the month, 248; discharged, 252; died, 8; highest number on any one day, 207; patients under x-ray treatment daily, 22; ambulance calls, 32; visitors to the wards, November 23, 408.

The Montreal General Hospital reports for November 251 admissions; 241 patients discharged; 23 died: the average in residence has been 193; the highest number on any one day has been 205; ambulance calls, 108. Typhoid fever cases showed 11 for the month as against 24 in 1901, same month.

Medical Council of the Yukon Territory.—The election of members for the medical council of the Yukon Territory, Canada, for 1902, resulted as follows: President, Dr. D. MacLeod; vice president, Dr. Barnett; registrar-secretary, Dr. A. E. Edwards; executive committee, Drs. Barrett, Sutherland and Alfred Thompson, with president and registrar as *ex officio* members.

To Check Spread of Tuberculosis in Montreal.—Last week a very largely-attended meeting was held in Montreal, presided over by Lord Minto, governor general of Canada, for the purpose of considering what measures should be taken for the prevention and cure of tuberculosis. A committee was appointed to create an enlightened public interest, and to further the employment of all means whereby it may be prevented or its ravages lessened.

To Vote for a Sanitarium for Toronto.—The City Council of Toronto has adopted the recommendation of the board of control to submit the following question to the ratepayers at the January city elections: Are you in favor of the city contributing \$50,000 toward the establishment of a sanitarium for the treatment of residents of Toronto suffering from consumption? This is in lieu of a money by-law for which there is said to be no legal authority.

Toronto and Trinity Medical Banquets.—The students and medical faculties of both Trinity Medical College and the University of Toronto held their annual banquets December 3. Professor Barker, '90, Toronto, of the University of Chicago, was present at the latter, and in proposing the toast of "The Professions," delivered an able address on the tendency of medical science. Probably the speech of the evening at the Trinity banquet was that delivered by Dr. T. S. Harrison, a general practitioner of Selkirk, Ont., who is still in active country practice at 75, who gave some very humorous experiences of practice in this province fifty years ago.

Personal.—Dr. Charles B. Shuttleworth of Trinity Medical College, Toronto, has succeeded in passing the examination for F.R.C.S. England; Dr. George W. Badgerow of the same city has passed the M.R.C.S. examination.—Dr. A. P. Crockett of Fredericton, N. B., returned, November 29, from England and the Continent.—Dr. Patrick B. Handyside, for five years in charge of the Naval Hospital at Esquimalt, B. C., has been replaced by Dr. Homer, who, with his family, is now en route from England.—Dr. Robert Wilson, professor of pharmacology and therapeutics in the University of Bishop's College, Montreal, is recuperating his health in the White Mountains.

Canada's Drink Bill.—The annual report of the Inland Revenue Department for the year ending June 30, just issued this month, states that the quantity of spirits produced during the year was 3,234,147 proof-gallons, as compared with 2,652,708 for the previous fiscal year. The people drank more spirits and beer last year than they did in the previous year. The quantity of spirits consumed was .796, as against .767 for the previous year. Beer was 5.102 as compared with 4.737 for

the previous year; and .090 of wine, as against .100 for 1901. Tobacco was the same as last year, the figures being 2,404. Of cigarettes there were consumed 134,236,034, as against 121,383,584 for 1901.

Toronto Insane Asylum.—Charges of a general character have lately been appearing in the society columns of one of Toronto's daily papers against the attendants and nurses of the Toronto Asylum for the Insane, of various cruelties against patients. Dr. Daniel Clark, the medical superintendent, replies to these, stating that they have no foundation, and that they have simply been the cause of much annoyance to the fifty-four persons who attend on the insane in that institution. This is the first time, he states, during the twenty-seven years of his superintendency in which charges have been made against the institution. He concludes his letter asking for names and facts, as he is anxious to refute such sensational allegations.

Public Health in Hamilton, Ontario.—Dr. Walter Langrill, medical health officer of Hamilton, Ont., presented his annual report at a meeting of the Board of Health of that city, December 1. It showed that during the year there were 691 cases of infectious diseases. Of these 106 were diphtheria, with 24 deaths; 64 were cases of typhoid fever, with seven deaths; five were cases of smallpox, with no deaths. The other cases were divided as follows: Scarlet fever, 97, 3 deaths; chicken-pox, 74, no deaths; mumps, 11, no deaths; measles, 222, 2 deaths; whooping cough, 112, 13 deaths. In all 744 deaths were registered, the death rate being 13.7 per 1000. The infant mortality was high, there being 137 deaths of children under the age of one year. Among the general causes of death were: Cancer, 45; heart trouble, 83; tuberculosis, 105. Hamilton has decided to report cases of tuberculosis to its medical health officer.

FOREIGN.

Influenza in England is reported as unusually severe.

Koch Summoned Again to South Africa.—The authorities of Rhodesia have appealed to Robert Koch to assist in the campaign against cattle plague, which is recrudescing.

Smallpox in Greek Archipelago.—A severe outbreak of smallpox is causing great loss of life in the Furni Islands, near Samos, Greek Archipelago, with almost no medical aid available.

Memorial to Widerhofer.—The emperor of Austria has ordered a portrait bust of Widerhofer which he intends to present to the St. Anna Children's Hospital, where the deceased was director for forty years.

Proposed Nurse Schools in France.—The present prime minister of France is a physician, and one of his first acts was to insist on the enforcement of a decree of 1893 calling on the municipal authorities of all towns where there is a medical school to organize a training school for nurses.

Distress in England.—The returns of the London Board of Trade show more unemployed unskilled labor than for ten years. There is much distress among the lower classes. There are 56,000 members of the Army released from service who will add to the number of the unemployed. Public subscriptions are being made for relief.

Anti-Nicotin Cigars Injurious.—The Austrian authorities announce that the chemical treatment of tobacco by Professor Gerold's method does not free the cigars from nicotine, while the chemicals used are more or less injurious. The tests showed .9 to 1.17 per cent. nicotine. The Austrian standard cigars contain 1.29 to 3.99 per cent.

Campaign Against Charlatans in Germany.—A civil suit was recently brought by a physician against a druggist at Breslau who advertised that he would cure all cases of stuttering under guarantee. The physicians managed the case well, and secured conviction and a fine. These cases against charlatans have hitherto been tried in the criminal courts.

The new home of the Paris Academie de Medecine was formally inaugurated by the president of the republic, November 25. The building adjoins the Ecole des Beaux Arts, and is in four parts, each four stories, one devoted principally to the famous library of the academy and one to the vaccination service. This includes stables for the calves, laboratories and waiting rooms for the persons applying for vaccination. The assembly hall is nearly twice as wide as it is deep, with a broad platform and 110 seats. The membership is limited to 100. The expense has been borne by legacies, private subscriptions, and some aid from the state.

LONDON LETTER.

Manufacture of Madmen a Result of the Law of Lunacy.

At the Medico-Psychological Society Sir William Gowers pointed out in an important paper a great defect in the existing Lunacy Laws, which tended to the production of insanity. The law decrees that all persons of unsound mind shall be treated alike, certified as insane, deprived of liberty, and placed under the control of the Commissioners in Lunacy. There is the large class of border-line cases, patients on the verge of insanity, some just over it. Many of them who might recover may be actually rendered insane by the process of being declared so, which certification constitutes. Such cases are very numerous. The nature of the process of certification can not be concealed from many patients, and is most clear to those to whom it is most harmful. Many on the brink of insanity are always haunted by the question: "Shall I go mad?" To them it sounds the knell of hope, for it gives the answer "You are mad." All the security the present law could give, and more, said Sir William Gowers, and all its harmful effects would be avoided by a system of notification. The time has certainly come when a commission should investigate both the work and the constitution of the board of lunacy, and the working of the lunacy act. The twelve years which have elapsed since the act was passed have furnished ample experience of its effect and deficiency. As a temporary measure he proposed that a brief enactment should be passed that the provisions of the lunacy act relating to private patients taken for payment should apply only to such cases as, in the judgment of the commissioners, need to be certified and detained in their own interest or for the safety of others. Among the audience were Sir William Church, Sir William Broadbent, and other distinguished physicians, most of whom addressed the meeting. The matter was unanimously referred to the Parliamentary Committee.

The Sanitation of Lagos.

Sir William MacGregor, the governor of Lagos, who is a medical man, has acquired a reputation as a sanitary pioneer which renders him quite unique among colonial governors. His efforts to improve the health of his deadly West African Colony have been more than once described in THE JOURNAL. At the invitation of the African Trade Section of the Liverpool Chamber of Commerce his excellency was entertained at dinner. Sir Alfred Jones, a Liverpool merchant to whose munificence the Liverpool School of Tropical Medicine is greatly indebted, and who has furnished the means for the various expeditions of that school for the purpose of investigating tropical diseases, presided. Several members of the staff of the school were present. Sir Alfred Jones spoke of the great debt the country owed to Sir William MacGregor for his efforts in West Africa. Replying, the governor said it had been his policy from the beginning in trying to improve sanitation in Lagos, not to confine their efforts to the people of one race or color, but to take along in one line both Europeans and natives. He had always been opposed on principle to the idea of separating the Europeans from the natives in order to avoid contracting malaria from the natives. Of course, the progress will be at a slower rate so far as Europeans are concerned, but if slow it will be sure, and this is the only way of arriving at the extermination of malaria in a place like Lagos. If malaria is mastered, he thinks there is a great future before Lagos. He had no doubt Lagos could be made a fairly healthy place. It is built on a sand island, having a sea breeze. It was announced at the dinner that a chair of tropical medicine had been endowed at University College, Liverpool, by special contributions amounting to over \$50,000, which included the munificent donation of \$25,000 from Sir Alfred Jones, and also \$2500 from the Hon. R. B. Blaize, Lagos. The committee will ask the authorities of University College to appoint Major Ronald Ross, C.B., as the first professor, and to call this chair the Sir Alfred Jones Chair of Tropical Medicine and Parasitology.

PARIS LETTER.

Renault and Danlos Against Mercurial Injections.

According to Drs. Renault and Danlos injections of mercury should be rarely employed, and resort should only be had to them when other methods such as ingestion or inunction have failed to produce any effect. They are less practical and sometimes dangerous.

The Treatment of Hypertrophy of the Prostate.

The treatment of hypertrophy of the prostate, which has entered on a new phase since prostatectomy has come into favor, was the subject of discussion at a recent meeting of the Society of Surgeons. Two of the younger school of surgeons, Dr. Al-

Cuba, and has a marked foreign accent in French, and Dr. Legueu, recently made surgeon of the hospitals, were the champions of this operation. Dr. Legueu had operated twelve times, with a fatal result in one case, an old man of 72, who had diseased kidneys and infection. Dr. Legueu considers it well to incise the urethra immediately, as it is sure to be cut later on in the operation, with doubtful results. He also advocates removing the whole of the prostate gland in two or three large portions. He had noticed as a complication extensive hemorrhage and a tearing of the rectum in two cases, though there was no subsequent fistula. Two patients were afflicted with incontinence after the operation, but Dr. Legueu, from his past experience, considers that this will only be temporary. Dr. Albarran has performed the operation forty-two times and has had but one death from cachexia in an old man seven years old suffering from double pyelonephritis. He does not consider that the indications can as yet be discussed, a statement which seems rather strange coming from a man who has operated so many times. According to Legueu, the size of the prostate is of paramount importance, and would justify the operation when dysuria is followed by retention. Calculi are also a good indication, as they may be removed by the same incision.

Curious Incident at the Society of Biology.

On October 18 the president of the Society of Biology announced to his colleagues that a lady, who was not of his acquaintance, had handed him two envelopes, one of which was to remain closed until the month of June, 1903, the other was to be opened before the society. On doing so, 10,000 francs (about \$2000) were found in it, and are destined to help publish the reports of the society. In writing of this, the editor of the *Presse Medicale* describes it as being very American.

Lucas-Championniere's Technic for Preparing Catgut.

At the Congress of Surgery, held in Paris last October, Dr. Lucas-Championniere, one of the first to introduce into France Lord Lister's principles of antiseptics, described his method for preparing catgut. It consists in Lister's method of placing catgut in a 20 per cent. solution of carbolic acid in oil. The only variante consists in placing it afterward in essence of turpentine. When an operation is to be performed Dr. Championniere places it in a 5 per cent. solution of carbolic acid. He always uses a large thread, as he considers that it is always readily absorbed.

Chloroform versus Ether.

Dr. Julliard of Geneva has reported 9289 cases of narcosis by ether without a single death, either during or after the operation. Asphyxia was overcome in three cases by artificial respiration. Bronchial pneumonia is due, according to this surgeon, to a lack of proper precautions, such as not covering the patient sufficiently and allowing him to get chilled, or else not removing the mucus which forms in the throat. Villar of Bordeaux has had 4000 cases of narcosis by ether without a single death, and Roux of Lausanne considers ether better than chloroform in narcosis. The A. C. E. mixture, which has been tried in England, Vienna and in Italy, has been employed also by Dr. Reynès of Marseilles. He has found it of benefit with old or weak patients, or when there were cardiac, renal, or broncho-pulmonary lesions, where the ether would be injurious for the lungs and chloroform might cause syncope. Chlorid of ethyl is being used more and more as a general anesthetic in some of the Paris hospitals, and the anesthesia produced will sometimes last as much as half an hour; 5 c.c. should be given every five minutes. After a period of anesthesia there is one of analgesia which may last as long as the period of anesthesia. When the operation is to last more than half an hour it is well to begin with chlorid of ethyl, and go on with chloroform or ether.

Sheets of Silver as a Dressing for Wounds.

Dr. Gauthier of Luxeuil described at the Congress of Surgery his use of silver threads and silver sheets in surgery. Instead of employing the ordinary silver thread, Dr. Gauthier uses tressed silver wire, made with threads only 0.08 mm. thick, and which, therefore, can cause no damage to the tissues. Sheets of silver, of extreme thinness, are indicated when wounds bleed easily, after skin-grafting, when there is eczema near a wound, and in all diseases of the skin, instead of the various plasters.

Suppuration of the Pancreas.

Dr. J. L. Faure, surgeon of the hospitals, described at one of the meetings of the congress two cases of suppuration of the pancreas which he had seen, and which have led him to think that this lesion is not so very infrequent. In one case a young

woman showed symptoms of a perforation of the stomach, and on being operated on she was found to have a large retrogastric collection of pus. The pancreas was gangrened, and a fistula, which persisted a long time, showed that the pancreas was the primary seat of the disorder. In the second case the patient, who had lost 50 kilos in weight, was supposed to be suffering from cancer of the stomach. It was found, however, that an enormous mass of adhesions had formed as a result of suppuration of the pancreas. Drainage was made and the patient is now quite cured.

Correspondence.

The Operative Treatment of Strabismus.

An answer to Dr. Geo. M. Gould's paper in THE JOURNAL of the American Medical Association, November 1, page 1106.

PITTSBURG, PA., Dec. 3, 1902.

To the Editor:—If in the following I shall attempt to refute some of Dr. Gould's arguments against the operative treatment of heterophoria and strabismus, I am fully aware of the difficulty of the task. With his overwhelming figures, the weight of his well-earned reputation, and the admirable spirit of sincerity which pervades every phase of his reasoning, Dr. Gould's position is formidable enough to intimidate any "deus minoris gentis."

However, I believe that in the seemingly impregnable wall with which the gallant defender of conservatism has surrounded himself, there are several weak spots; some of the fundamental stones are loosened already by the able efforts of others, and here and there I even find that the builder has altogether neglected to support his foundation with concrete material. In fact, he even furnishes us with the weapons to upset his structure. To speak less metaphorically, and to go right "in medias res," the anatomic relation of Bonnet's capsule to the tendons and its bearing on the conditions as created by tenotomy have been completely ignored in Dr. Gould's chain of evidence. To anyone familiar with the fact that Bonnet's capsule is reflected on the tendons where they pierce the capsule and becomes continuous with the fascia of the muscles (lateral invagination) the effect of severing the tendon must be self-evident: The muscle will exert a certain amount of traction on the capsule; if we now sever the connective tissue between the tendon and the capsule, a procedure which Dr. Gould sees fit to deride as "post-graduate," the muscle will glide back farther into the orbit. For illustration we assume that the internal rectus of the right eye has been severed. Abduction will immediately take place, caused chiefly by the action of the external rectus. The gap thus formed will be the result of two factors: tonicities of the rectus internus and abduction through the rectus externus. While I readily admit that this abduction is partly neutralized by the active effort of the patient to lessen the traction of the wound, I can not see how reinsertion at the former line of insertion can possibly take place, since there remains a gap which no amount of voluntary or involuntary compensation on the part of the other muscles will completely overcome.

This is one theoretical "scrap of evidence" according to which it is utterly impossible that the tendon should become reattached to its former line of insertion, provided, however, that we have severed it completely. All surgical analogy helps to strengthen this assertion. There is not one tendon in the human body which, severed and left alone, will reinsert at its former point. If restitution of the function of the muscle actually takes place it can not be due to any other agency than the one pointed out by Dr. Gould himself, namely, regrowth of tissue. But who will deny that in the latter case—filling of the gap through new tissue—an actual lengthening of the muscle has taken place?

The mere admittance of this possibility renders irrelevant the argument that a tendon will not grow on an unabraded, uninjured surface. However correct this assertion may be, it does not come into consideration in our case for the above reason that the gap formed by the operation will be bridged over by newly-formed connective tissue which finally will unite the two surfaces, and, by its interposition, will add to the total length

of the muscle. If it happens occasionally that this bridge does not develop, it does not necessarily imply that no insertion whatever will take place. What Dr. Gould pronounces the invariable rule, to-wit, that the surface behind the stump is unabraded and uninjured, seems to me, on the contrary, a very rare exception. The technique of the operation makes such abrasions more than probable, and if there were in my mind any doubt left, my practical experience of about two score of repeated tenotomies would remove even the slightest shadow of such a doubt. The rule is that in repeated tenotomy we shall find the line of insertion moved back. So typical have I found this condition that in a second tenotomy on the same muscle I invariably make the conjunctival incision from 2 to 4 mm. farther back than in a first tenotomy.

Another equally good *modus restitutionis* is that in which filling of the gap through newly-formed tissue is combined with insertion behind the former line of attachment. In such cases we find a broad surface instead of a line of attachment, a condition which clearly indicates that the surface behind the stump was abraded during the first tenotomy. But leaving aside even these practical "scraps of evidence," there is another factor which has not been considered by Dr. Gould. Assuming that no reattachment has taken place at all (for instance, immediately after the operation), has the severed muscle lost all of its power over the eyeball? By no means. The traction on Bonnet's capsule still remains and will prevent the antagonist from exerting his full force. If this were not the case, how could we explain the formidable amount of adduction that remains after complete severance of an internus? Merely by the action of the auxiliary adductors? If so, why will the severing of the belly of the muscle produce such a marked decrease in adduction, or abduction, as the case may be?

So far, all of our arguments have been directed against the theory of reinsertion at the old place, together with the establishment of a *status quo antea*, on which theory Dr. Gould bases his assertion: "Hence, in a few months or a year all the old troubles return after needless surgical intervention."

For obvious reasons we shall not condemn all of Dr. Gould's conclusions because one of his premises was incorrect. Thus we perfectly agree with him as regards the one feature that tenotomy can do little or nothing toward removal of the primary causes of the large majority of strabismus cases. We shall be able to correct slight degrees of astigmatism by relieving some of the lateral pressure on the globe; we can remove part of the strain on the antagonist and thus enable the latter to respond more promptly to impulses; we bring the optic axis in a more favorable position for macular vision, where macular vision is still possible, but, unless conditions are especially favorable, some of the old troubles (not all of them) will return, not because the tendon will reinsert at the old line of attachment, but because the primary factors can not be eliminated in all cases.

All of these objections can not have any bearing on the important role which tenotomy, eventually combined with advancement, plays as a preparatory measure for the treatment of some of the above troubles. Take, for instance, all those cases of heterophoria and strabismus in which the primary factor is hypermetropia, with its excess of accommodative impulses, which implies at the same time an excess of convergence. An immense expenditure of nervous energy, time and money may be saved to the patient if we remove the deficit in abduction by a suitable operation on the hypertrophied internus. The correction of the refractive errors will be simplified, the time of the treatment shortened and the appearance of the patient permanently improved; in other words, surgical intervention will smooth the path for intelligent non-surgical treatment.

Nevertheless, Dr. Gould assures us that with the exception of one (!) case he never saw the results of an operation in heterophoria or strabismus of which he should be proud to say he did it! Considering the sincerity, enthusiasm and trustworthiness of the distinguished Philadelphia author, there remains nothing for us but to express our regret that he should be the victim of what I am inclined to take for an extraordinary coincidence. With Dr. Risley I offer as an ex-

planation for this strange phenomenon that the scores of successful operations that he must needs have performed himself never returned to his view, simply because they were cured or perfectly satisfied with the results obtained.

Having thus established the fallacy of some of Dr. Gould's premises, I proceed to examine his arguments in favor of non-operative treatment. In this respect, it seems to me, Dr. Gould has committed the error of "reckoning without his host." While this would not necessarily imply the scientific untenability of his position, it will erect an unsurmountable barrier to the indiscriminate acceptance of his therapeutic suggestions. "Tiat principium, pereat mundus," is a very dangerous maxim. A therapeutic measure, be it ever so correct, must be feasible before it can be universally adopted. Applied to our case, we must always bear in mind that we have often to contend with factors which are absolutely beyond our control. Of these factors I mention here the intellectual standard of the vast majority of our patients, their ages, their individual wishes, the time required and inconvenience caused by prolonged treatment, and last, but not least, the financial circumstances of the average patient. Once more I repeat, that all these objections are not directed against the correctness of the assertion that the non-surgical treatment of strabismus is the more accurate, scientific and (occasionally) the more harmless mode of therapeutics, but against its practical feasibility. We must reckon with circumstances as they are and not as they might be, which does not, at the same time, exclude our duty to work toward a state of conditions, as they should, or will be, in the far, far-away future.

Until the arrival of that millenium state, when the public will realize the necessity of having their babies' eyes examined by the expert; until the latter, including those who had the misfortune of an European education, with all its "ophthalmologic error and therapeutic sin," will be able to use retinoscopy to such a degree of accuracy that they may determine the refractive errors of the fetus in utero; until the dawning of that Bellamic era of prosperity which will enable us to engage a couple of special nurses for our little tots—not until then will the conservative treatment of strabismus become uniformly adopted.

The sovereign indifference which Dr. Gould exhibits with reference to the cosmetic possibilities of tenotomy is surprising, to say the least. It has been my experience, which I believe will be verified by the majority of my esteemed confrères, that 95 out of every 100 patients who consulted me for correction of an existing squint, did so in the expectation of having their unsightly deformity removed, and not for the relief of asthenopia. From the standpoint of the average patient the importance of correction of his refractive errors dwindles into insignificance as compared with that of his deformity. As a matter of fact, can we hold him responsible for this indifference to his ametropia or astigmatism, if he suffers no inconvenience whatever from the latter defects, if time and again we meet with patients who had been unconscious of their ametropia up to the very day that they consulted us for the purpose of having their eyes "straightened"? Besides, Dr. Gould's allusion to the *laissez aller* policy is not very happily illustrated by the example of "the leg that we do not strap out of the way"; a man may see with one eye, and see pretty well, but I have yet to see the first man who walked on one leg.

In the introductory lines of this paper I have taken the liberty of pointing to the fact that Dr. Gould has furnished us with the tools for upsetting his structure. "Every good oculist," he says, "has hundreds of patients who have no deformity and who have binocular vision—so long as their spectacles are in place. Raise the lenses and instantly there is strabismus! That is a demonstration convincing to everyone." Indeed it is! A more striking illustration could not have been found in the whole material of evidence against the failures of conservatism. Just imagine the happiness naturally arising from the consciousness that the mere raising of the lenses instantly restores the strabismus! The happiness of such a patient can only be surpassed by that of another, to whom we have just brought the glad tidings that it will probably take ten years to cure his strabismus.

In the foregoing lines we believe to have amply demonstrated to what fallacies the rigid adherence to any one system may lead. It has led one of America's foremost oculists to denounce surgery as the "despair of medicine"! A statement like the above, coming from such an authoritative source, involves an imminent danger to both the profession and the public. It will be taken up by every quack in the country and serve as a ready reference in their pompous advertisements, to cure "crossed eyes, cataracts, films and scums" without the use of the knife.

It is not within the scope of this paper, nor within the ability of its writer, to point out all the tortuosities, grades and obstacles in the path which alone can, will and must lead to salvation. I will, therefore, restrict myself to the summary statement that the solution of the problem lies, in my opinion, in the happy blending of conservatism with radicalism. The promiscuous adoption of the one is as dangerous as the wholesale condemnation of the other.

In conclusion, I deem it my duty to express surprise at the low opinion that Dr. Gould seems to entertain with regard to European oculists. The statement that "there is probably not an 'ophthalmic surgeon' in all Europe who can use this method [retinoscopy] with accuracy"—not to dwell on the difficulty of furnishing the proof for such an assertion—bears every mark of improbability in consideration that this method is practiced by several of Europe's best oculists, almost in total preference to any other method of refracting children.

Another criticism of the same order is equally unjustified. Quoting a paragraph in Dr. Fuchs' text-book, Dr. Gould says: "In anisometropia we give the same glasses for both eyes, or correct only one eye and place a plane glass before the other." Commenting on this paragraph, Dr. Gould remarks: "I set this sentence out in capital letters as displaying as much ophthalmologic error and therapeutic sin as could easily be gathered into so many words."

In the first place, the quotation is not correct. The text before me (page 659, translation by Dr. Duane, 1896), reads: "We *therefore* prefer in anisometropia either to give the same glasses for both eyes, or to correct only one eye and place a plane glass before the other." In connection with the preceding and following sentences and duly considering the word "therefore," the sentence gains an altogether different aspect. After stating that the obvious course would seem to be to correct the anisometropia by ordering different glasses for the two eyes, Dr. Fuchs remarks that this measure proves impracticable in *most* cases; mentions the symptoms arising from anisometropia of a high degree, gives his explanation, which I believe to be theoretically and practically irreproachable, and finally, by inserting the above quoted sentence, "we *therefore* prefer," etc., calls our attention to the method to be adopted for those cases in which we have failed to give satisfaction by prescription of different glasses, referring chiefly to glasses with a different index (+ or —), as can be readily seen from the connection with another preceding sentence.

A. S. SIGMANN, M.D.

COMMENT BY DR. GOULD.

A more careful reading of my paper would have resulted in an avoidance of a number of errors in Dr. Sigmann's courteous criticism. I will not take up valuable space to detail these, except in one illustrative instance: In the body of my article it is expressly stated that the excerpt wherein occurred the quotation from Fuchs was from an article written ten years ago. I do not garble quotations, and, when written, the quotation was verbatim from the last edition. That four years later Fuchs had progressed to the position illustrated by Dr. Sigmann's quotation is encouraging. What will the progress be in the next four years?

As to the misuse of truth by quacks, that does not concern me. To refuse to accept and state truth because of such dangers is to accept the ethics of the quack. As to European oculists, they are the peers of any as regards pathology and inflammatory and surgical diseases. But proper refraction prevents both classes of diseases. Of proper refraction European oculists know almost absolutely nothing. In this their work is the most absurd. A patient of mine consulted the

most famous "ophthalmic surgeon" of Germany last summer, and for an enormous astigmatism (of which the surgeon was utterly incurious) he ordered massage of the eyes by the patient. For blepharitis, due to refractive error, another famous man told another patient to squeeze out the secretion of the Meibomian glands with her fingers. A great French oculist ordered simple isometric spherical lenses for astigmatic anisometropia, and expressed indignant surprise at the idea that he, the oculist, should have kept any record of the lenses he had ordered. I could enumerate many such laughable instances. But such things are common enough in America also, and to gibe at the refraction of the *fetus in utero* does not make them less common.

It is true that extremes are dangerous and that the middle-of-the-road is usually the safest and truest. Not always, however! A compromise, if for the sake of compromise, may be a worse error than either extreme. The time is not far past when one who should have proposed to cure strabismus (and surely heterophoria!) by any other method than operation would have been looked on as crazy.

GEORGE M. GOULD, M.D.

Midshipman Aikin and Vivisection.

PHILADELPHIA, Dec. 5, 1902.

HON. JACOB H. GALLINGER,

Chairman of the Senate Committee on the District of Columbia, Washington, D. C.

My Dear Sir: As you have repeatedly introduced bills into the Senate for the purpose nominally of regulating experiments on animals in the District of Columbia, which bills, however, if they had become laws, would in fact have prohibited many, if not all of them, I deem it my duty to call your attention to the case of Midshipman Aikin of the United States Naval Academy, who was recently injured in a football game. My reason for doing so is to show you by a single concrete example that knowledge gained by animal experimentation is an immense boon to humanity and that, therefore, such experiments should be heartily encouraged.

The facts of Mr. Aikin's case are as follows: When I first saw him, three days after the accident, I found that he had been unconscious for a half hour after the accident and ever since then had complained bitterly of headache, which he located always in the forehead. Mentally he was very dull, though not comatose. His pulse was slowed down to 52 instead of being 72, the normal. Soon after the accident he began to develop convulsions, first in the right leg, afterward in the right arm also, the right arm being finally the chief seat of the convulsions. When they were very severe they involved the left side also. The face was never involved. In six hours and a half after I first saw him he had 24 of these attacks, all limited to the right arm. They were not attended by any loss of consciousness. They exhausted him very greatly, especially when they were excessively severe. Several times it was necessary to give him chloroform.

There was no fracture of the skull. The only physical evidence of any injury was a very slight bruise at the outer end of the left eyebrow.

Had I seen this case before 1885 I would have been unable to explain why the spasms were chiefly manifested in the right arm, and from the evidence of the slow pulse, the headache, the stupor, the bruise in the left temple, etc., I would have been justified in inferring that probably the front part of the brain was injured at the site of the bruise. Had I opened his skull at that point I would have found a perfectly normal brain and have missed the clot. The young man, therefore, would have died, whether his skull had been opened or not.

In 1902 observe the difference. As a result of the knowledge derived from experiments on animals which have located precisely the center for motion of the right arm on the left side of the brain near the top and a little in front of a vertical line drawn through the ear, and disregarding entirely the site of the headache and the bruise, I reached the conclusion that there had been a rupture of a blood vessel within the head, which had poured out a quantity of blood, and that the

situation of the clot should correspond to the "arm center." The location of this arm center was far away (about three inches) from the location of the bruise, and its position was fixed absolutely as a result of experiments on animals, confirmed later by many operations on human beings and also by postmortems.

As soon as the skull was opened at this point the clot was found, its thickest point being exactly over the arm center and nine tablespoonfuls of blood were removed, with the result that the patient's life has been saved. The blood had first been poured out over the "leg center," which is located a little higher up than that for the arm. This explained the early spasms in the right leg. The clot did not extend, however, further down than the arm center. This explained why the face was never convulsed, for the "face center" lies just below that for the arm.

I think if you were to ask the parents of this young man how many animals they would be willing to have sacrificed in order that their son might have his life saved, there would be no doubt of the answer. Indeed, had it been your own son, I can not doubt the answer. But this is only one of hundreds of cases in which a similar exact localization has been made by many surgeons, both in Europe and America. Yet, by a curious coincidence, in the very same issue of a Baltimore newspaper containing a reporter's account of the successful operation on Midshipman Aikin there is a letter signed by an active antivivisectionist agitator, which, among other misstatements and misrepresentations usually found in such publications, asserts that "brain surgery is disregarded."

If the laws which you and your friends advocate were in force, the conditions for scientific investigation in medicine in this country would be quite as deplorable as those in England. For example, when Lord Lister, who has revolutionized modern surgery, largely as a result of such experiments, wished to discover possibly some still better way of operating by further experiments, he was obliged to go to Toulouse to carry them out, as the vexatious restrictions of the law in England practically made it impossible for him to continue there these pre-eminently humane experiments.

Again, when Sir T. Lauder Brunton in London started a series of experiments on animals to discover an antidote for the cobra and other snake poisons of India, where every year 20,000 human lives are sacrificed by snake bites, these beneficent researches were stopped by the stringent British laws to protect animals. Meanwhile half a million of human beings have hopelessly perished.

Who, I may ask, is the more humane; he who, doubtless with the best and sincerest motives of love for dumb beasts, would prohibit experiments on animals and thereby prevent the acquisition of such knowledge and so compel surgeons to stand with folded arms and see innumerable lives thus needlessly sacrificed; or he who, by properly instituted experiments, would discover such new truths and apply them to the service of humanity?

The antivivisectionists have frequently denied that surgeons have learned anything from such experiments. I presume that I may be considered a competent witness as to the source, at least, of my own knowledge, and I state with the greatest positiveness that without the knowledge derived from experiments on animals which have demonstrated the facts of cerebral localization, I should never have been able to locate the clot in Mr. Aikin's head and to remove it, nor would I have been able in the last fifteen years to locate numerous tumors and other brain troubles and relieve many of them. What is true of myself is equally true of other surgeons.

In view, therefore, of the evident and positive benefit of such experiments, I trust that you will be willing to desist from further efforts at such repressive and, as I regard it, most inhumane and cruel legislation.

As this matter is of vital importance to the well-being of the entire community, I shall take the liberty of giving this letter to the press as soon as you have received it.

Yours very respectfully,

W. W. KEEN,
Professor of Surgery, Jefferson Medical College.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

WHAT STATES ACKNOWLEDGE DIPLOMAS?

CHICAGO, Nov. 28, 1902.

To the Editor:—Kindly inform me through THE JOURNAL what states acknowledge college diplomas or Illinois licenses.

R. S. BENTLEY.

ANS.—The following states accept diplomas from a recognized college as a qualification for license to practice: Arkansas, Colorado, Kentucky, Michigan, Nebraska, Nevada, New Mexico, South Dakota and Wyoming. It is optional with the Board in Kansas. In Colorado those not holding recognized diplomas are granted licenses after passing an examination. An Illinois license is possibly recognized in Wisconsin and Indiana, as well as in Michigan, but we have not received the latest information in regard to the matter.

TECHNIC OF TONGUE TRACTION.

GOSHEN, IND., Nov. 27, 1902.

To the Editor:—Please give me, through your columns, the technic of Laborde's method of resuscitating the drowned; also state what is the important factor in the method as it is practiced that causes a return of the voluntary respirations in the patient. How many times to the minute should these rhythmic tractions of the tongue be practiced?

B. T. WILLIAMS.

ANS.—Laborde's method of resuscitating the drowned consists in rhythmic tractions on the tongue at the rate of the normal respiration or a little slower. The theory of its action is that it is a reflex one. The tongue should be drawn upward and not over the lower jaw.

HAWAIIAN PRACTICE RULES.

MINNESOTA, Dec. 1, 1902.

To the Editor:—What is required to obtain a license to practice medicine in the Sandwich Islands? To whom would one apply for such license?

G. F. P.

ANS.—To practice medicine in Hawaii a license is required, given after examination by the Board of Health. Dr. J. S. B. Pratt, Honolulu, is the executive officer of the board.

State Boards of Registration.

South Carolina Litigation.—Some time ago the South Carolina Legislature exempted four-year course graduates of medical colleges in that state from examination. A class that had taken a course of three years applied for the free licenses, which were refused. One member contested the matter, and the Supreme Court has just decided in favor of the board. The class will, therefore, have to be examined.

Kansas Board Can Revoke Licenses.—An important decision has been rendered for the Board of Registration of Kansas, affirming their power to revoke the licenses of practitioners whom they consider unfit to practice. One Meffert of Emporia was accused of gross immorality, and the board revoked his license. He applied for an injunction and it was refused. The ruling states that the right to practice medicine has been decided not to be a right of citizenship, and the judge declares that the board has the right to refuse that privilege to anyone until he has proven his fitness.

Michigan Report.—The Michigan State Board of Registration in Medicine reports, by Dr. B. D. Harison, secretary, Sault Ste. Marie, the examination held at Lansing, October 14-17: Number of subjects examined in, 19; questions, 190; percentage required, 75; written examination; number examined, 14; passed, 8; failed, 6.

		PASSED.

Book Notices.

THE PRACTICE OF SURGERY. A Treatise on Surgery for the Use of Practitioners and Students. By Henry R. Wharton, M.D., Clinical Professor of Surgery, Woman's Medical College of Pennsylvania, and B. Farquhar Curtis, M.D., Professor of Clinical Surgery and Adjunct Professor of the Principles of Surgery in the University and Bellevue Medical College of New York. Profusely Illustrated Third Edition. Cloth. Pp. 1241. Price, \$6.50. Philadelphia and London: J. B. Lippincott Co. 1902.

The articles in this edition have been fully revised and a large amount of new matter introduced. The editors have condensed the facts in such a way as to bring as much as possible within the compass of the volume. It seems to us to meet the needs of a text-book fairly well. The authors have signed their separate articles, but endorse the practical conclusions throughout the work so that we notice no serious defect in the work, such as often happens in composite works from overlapping of subjects or difference of individual views. The illustrations are very good.

DEATH AND SUDDEN DEATH. By P. Brouardel, Professor of Medical Jurisprudence, Dean of the Faculty of Medicine, Paris, and F. Lucas Benham, M.D., B.S. (Lond.), M.D. (Adelaide), Member of the Royal College of Physicians of London. Second Edition. Cloth. Pp. 336. Price, \$3.00. New York: Wm. Wood & Co. 1902.

The translator says that in preparing the former edition he had felt with some regret that the treatise was too brief, and that he has in this edition met this difficulty by numerous additions enclosed by brackets. These seem to us to add material to the value of the work. For a book of reference on the questions, medicolegal and otherwise, relative to sudden death it is an excellent one; in fact, we know of no other in our language which fills its place within its compass.

THE PRACTICAL MEDICINE SERIES OF YEAR BOOKS, comprising Ten Volumes of the Year's Progress in Medicine and Surgery, Issued Monthly. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Volume X. Skin and Venereal Diseases, Nervous and Mental Diseases. Edited by W. L. Baum, M.D., and Hugh T. Patrick, M.D. September, 1902. Cloth. Pp. 245. Price, \$1.25. Chicago: The Year-Book Publishers.

This tenth volume of the series gives the principal advances made in these two branches of medicine during the year, and like the other handbooks of the series, will be found very useful to the general practitioner.

Marriages.

S. S. MEYERS, M.D., Centerville, Kan., November 26.

WALTER WALDEN, M.D., to Miss Albertine Wilhelm, both of Chicago, December 3.

CHARLES REED, M.D., Chicago, to Miss Ethelyn Eaton of Beloit, Wis., December 2.

WILLIAM T. SHIPP, M.D., to Mrs. Carrie B. Ward, both of Coffeyville, Kan., November 24.

THOMAS R. BROWN, M.D., to Miss Jeanne McComb Albert, both of Baltimore, November 27.

CHARLES T. GRAHAM-ROGERS, M.D., to Miss Mary C. Church, both of New York, November 26.

HOWARD TICKLE, M.D., to Miss Virginia Jarrett, both of Charleston, W. Va., November 26.

GEORGE W. MAX, M.D., to Miss Isabelle Mitchell, both of Willimantic, Conn., November 28.

C. CHURCHILL CARMALT, M.D., New York City, to Miss Alice Kidd of Tivoli-on-Hudson, December 4.

HERMAN L. NIETERT, M.D., to Miss Katherine Ziegenhein, daughter of the ex-mayor of St. Louis.

CAMILLE COTE, M.D., Marlborough, Mass., to Miss Edna Whitcomb of Quincy, Ill., November 27.

ALPHA D. UPDEGRAFF, M.D., Anthony, Kan., to Miss Sadie Eaton of Kansas City, Kan., November 24.

SAMUEL G. STAPLES, M.D., Washington, D. C., to Miss Douglas Maryon of Biloxi, Miss., November 26.

LEWIS M. BUNNELL, M.D., Tecumseh, Mich., to Miss Charlotte Alice Trotter of Rochester, N. Y., November 25.

ALVIN L. LIGHT, M.D., Dayton, Ohio, to Miss Carlotta Thomas, National Military Home, Ohio, December 3.

RICHARD F. HARRELL, M.D., Ruston, La., to Mrs. Sarah Page McKee of Philadelphia, at Ruston, La., November 23.

JOHN ROGER HAYNES, M.D., East View, N. M., to Miss Juanita Armijo of Albuquerque, N. M., November 22.

ELAM R. WRIGHT, M.D., Alton, N. H., to Miss Anna Murray of Valley Falls, Kan., at Alton, N. H., November 27.

WILLIAM SIMS BOYD, M.D., Jersey City, N. J., to Miss Florence Augusta Evans of Orangeburg County, S. C., at Columbia, S. C., November 19.

Deaths.

Henry P. Fricker, M.D. Columbian University, Washington, D. C., 1860, for several years superintendent of the State School for the Blind, Columbus, Ohio, and surgeon of the Twentieth Ohio Infantry, U. S. V., in the Civil War, died at his home in Ashtabula, November 27, after an illness of several weeks, aged 66.

Gregor C. McGregor, M.D. New York University, 1850, who had practiced in Texas for half a century, and was one of the organizers of the Washington County Medical Association, and at one time its president, died at his residence in Waco, November 23, after an illness of several months, aged 78.

H. Melville Smith, M.D. College of Physicians and Surgeons, New York, 1871, for 18 years a practitioner of Jersey City, and president of the medical board of Christ Hospital, died at his home in South Orange, from nervous prostration, November 28, aged 55.

Mirza N. Benjamin, M.D. University of Vermont, Burlington, 1864, a native of Oroomiah, Persia, and one of the youngest surgeons in the Civil War, died at his home in Dunkirk, N. Y., after an illness of nearly five months, aged 59.

William H. Stayner, M.D. College of Medicine of the University of Illinois, Chicago, 1898, aged 42, committed suicide, December 3, by shooting himself in the head and then throwing himself in front of a rapidly-moving railway train.

Henry W. Ochsner, M.D. Johns Hopkins Medical School, Baltimore, 1902, a member of the medical staff of the Johns Hopkins Hospital, died at that institution from typhoid fever, November 25, after an illness of 18 days, aged 25.

Charles M. Lee, M.D. Geneva (N. Y.) Medical College, 1850, died at his home in Fulton, N. Y., November 28, after a short illness from pneumonia, aged 77. He had served as president of the Oswego County Medical Society.

Allan P. Ebbert, M.D. Starling Medical College, Columbus, 1889, died from pneumonia, after a short illness, November 28, at his residence in Atlanta, Ga., aged 39. He served as surgeon through the Spanish-American War.

Harry Luther Kiehl, M.D. Western Pennsylvania Medical College, Pittsburg, 1896, of Fayette City, Pa., died suddenly at his father's home near Bentleyville, Pa., November 29, from heart disease, aged 34.

Benjamin C. Toler, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1859, died at his home in Astoria, Ill., from cancer of the stomach, November 30, after an illness of five months, aged 74.

James Allen, M.D. Berkshire Medical College, Pittsfield, Mass., 1849, died at his home in Richford, N. Y., aged 75. He served in the Civil War as surgeon of the Eighty-ninth Infantry, N. Y. Volunteers.

Joseph Clark, M.D. London University (Guy's Hospital), England, 1847, who had practiced in Baltimore for 30 years, died at his home in that city, November 27, from Bright's disease, aged 78.

George F. Monahan, M.D. Maryland Medical College, Baltimore, 1900, of Woonsocket, R. I., died suddenly, November 23, at Saranac Lake, N. Y., where he had gone on account of ill-health, aged 27.

Norman Garibaldi Ross, M.D. Michigan College of Medicine and Surgery, Detroit, 1896, died from taking an accidental dose of strychnin, November 27, at his home in Detroit, aged 27.

William P. Clower, M.D. Pennsylvania Medical College, Philadelphia, 1855, for many years a resident of Moultrie, Ga., died at his home in Cairo, Ga., November 17, from paralysis.

David H. Montgomery, M.D. Pennsylvania Medical College, Philadelphia, 1852, died at his home in Millinville, Pa., November 28, from paralysis, after a short illness, aged 68.

Francis M. Phillips, M.D. Tulane University, New Orleans, of Lexington, Miss., 1892, was accidentally shot and killed, November 23, while hunting near Ruleville, Miss., aged 33.

William H. Ingram, M.D. Memphis (Tenn.) Hospital Medical College, 1897, died at his residence in Kenedy, Texas, November 24, after an illness of more than a year.

James D. Abels, M.D. Louisville (Ky.) Medical College, 1894, of Grant, I. T., died in Paris, Texas, November 20, after an illness of two months, from typhoid fever.

William A. Guild, M.D. Harvard Medical School, Boston, Mass., died at his home in Sanford, Fla., November 21, from paralysis, after a short illness, aged 75.

J. Landis Seitz, M.D. Jefferson Medical College, Philadelphia, 1882, died suddenly at his home in Harrisburg, Pa., November 28, from apoplexy, aged 46.

John M. Welsh, M.D. Cincinnati College of Medicine and Surgery, 1869, died at his home in Deersville, Ohio, from cancer, November 21, aged about 60.

Samuel Aughey Suloff, M.D. Rush Medical College, Chicago, 1882, of Patterson, Pa., died suddenly from heart disease, at Rockville, November 23, aged 45.

Adam E. Robson, M.D. Medical College of Ohio, Cincinnati, 1888, died suddenly from heart disease, November 27, at his home in Cincinnati, aged 40.

Frank R. Agur, M.D. Toledo (Ohio) Medical College, 1893, died at his residence in West Toledo, November 30, as the result of an overdose of cocaine.

Curtis A. Wood, M.D. Dartmouth Medical College, Hanover, N. H., 1878, died at his home in Dublin, N. H., December 1, from diphtheria, aged 56.

Deaths Abroad.

Dr. L. Landois, professor of physiology at Griefswald. His "Manual of Physiology" has been translated into several languages, and his contributions to science include the discovery of the cortical, thermic center, and much research on transpiration, histology of the nerves, etc. He was born in 1837.

Dr. M. Wilde of the Institute of Hygiene at Munich, a member of the editorial staff of the *Munchener Med. Woch.*—Dr. L. Marvaud, chief of the French military sanitary service. His property was bequeathed to establish a fund for the widows of Army surgeons in need.

Dr. F. Dornbluth, one of the leading authorities on hygiene in Germany, and indefatigable in its promotion, died at Frankfurt-on-Main, aged 77. Among numerous works in this line were popular treatises on the hygiene of the home, of athletics, of the school, etc.

Association News.

New Orleans in May.

There has been expressed a fear that the climate of New Orleans in May is liable to be too warm for comfort. We are assured, however, that there need be no fear on this account, for May is one of the pleasantest months in the year there. Considering that the Association meeting will be held in the first week of May, it is not at all likely that the heat will be oppressive. Touching on this matter the current number of the *New Orleans Medical and Surgical Journal* says:

MAY IN NEW ORLEANS.

"The blushing spring bears witness to the tranquil season, when the iris flecks the fallow fields in tones of gray and brown and blue, and where the dogwood beckons in the swampland and clovers whiten roadsides with their fragrant bloom. The magnolia blossoms to the tune of twittering birds, while roses and the jasmines, fresasias, columbine and the mellow orange flowers make the May time sweetest of the year.

"The balmy nights are redolent with odors of Nature's fruitful promise; too soon for broods of festive culex, or of gnat; while toothsome fish and fowl are plentiful.

"May is the month of New Orleans' months. When the sun shines with glory and with fended ray; when starlight seems brighter, because the nights are less marked by clouds; when the dew is early and the showers have grown less frequent in a cloudless sky.

"The days grow longer in the May time and twilight halts, slow to speed the passing day; from out the open windows float upon the willing air the sounds of home. This is the season.

And while the time or day is not of our choosing, we, of the medical guild, are glad to say to the members of the American Medical Association, brothers in the art, come in May!"

One-Half Rate Assured.

Dr. Thomas H. Stucky, chairman of the Committee on Transportation, notifies us that the Southeastern Passenger Association has given one fare for the round trip for the New Orleans meeting. That association will recommend to the other passenger associations that this rate be adopted. Since the passenger association covering the territory in which the meeting is to be held usually sets the rate for the whole country, there is no doubt that all the other passenger associations will adopt the recommendation of the Southeastern, and that we will have half rates from all over the country.

New Members.

New members for the month of November, 1902:

ALABAMA.

Sellers, Ira J., Birmingham.

CALIFORNIA.

Hashimoto, Shingo, San Francisco.
Coffey, W. B., San Francisco.
Banta, W. P., San Francisco.
Champion, Jos. Austin, Colton.
Hawkins, J. H., St. Helena.
Langdon, S. W. R., Stockton.
Allen, Lewis W., San Francisco.
Hawkins, S. J., San Francisco.
Pond, Henry May, Alameda.
Stratton, R. T., Oakland.
Owen, J. A., Red Bluff.
Watters, Peter Kemp, Watsonville.
Cheney, Wm. Fitch, San Francisco.

COLORADO.

Hess, Wm. L., Denver.
Cosby, O. W., Tabasco.
Schavoir, Frederick, Stamford.
Thorp, Rollin L., Denver.
Courtney, J. E., Denver.

CONNECTICUT.

Cooper, L. E., Ansonia.
Anderson, Arvid, New Britain.
Ramsey, Otto G., New Haven.

DELAWARE.

Briggs, H. W., Wilmington.
Forrest, G. W. K., Wilmington.
Wm. M. Ogle, Delaware City.

DISTRICT OF COLUMBIA.
Baler, Geo. K., Washington.

FLORIDA.

Blount, B. B., Punta Gorda.
Liell, Edw. N., Jacksonville.
Marsh, Chas. Franklin, Pensacola.
Skaggs, P. T., Miami.

GEORGIA.

Cox, Wm. James, Pennington.
Lewis, F. L., Camilla.
Harrison, E. S., Thomson.
Bryan, John A., Pendergrass.
Collier, T. J., Griffin.
Thomas, Dennis Lang, Eatonton.
Ainsworth, Harry, Thomasville.

IDAHO.

Dubois, J. K., Boise.
Hannberg, J. J., Oakley.
Higgs, A. A., Soldier.

ILLINOIS.

Bleuler, Ernest A., Carlinville.
Adams, A. R., Tennessee.
Haskell, Hiram A., Chicago.
Fowler, Edson B., Chicago.
Fox, John Sebastian, Chicago.
Merrill, Julia M., Chicago.
Barker, M. R., Chicago.
Roberts, Norman J., Waukegan.
Ray, D. S., Cuba.
Peterson, S. G., Rutland.
Oyler, H. S., Lincoln.
Bonar, B. L., Streator.
Sheetz, C. R., Freeport.
Bane, Samuel, Ellsworth.
Shaw, A. M., Ottawa.

INDIANA.

Roney, David C., Milan.

INDIAN TERRITORY.

Wear, John B., Poteau.

IOWA.

Pierce, W. F., Carson.
Boyd, C. E., Newton.
Scott, W. A., Maquoketa.

Smith, Jessie V., Winterset.
Shively, J. D., Des Moines.
Breene, Frank Thomas, Iowa City.
Victor, Albert Lycurgus, Kalo.
Birney, C. E., Estherville.
Cole, J. H., Council Bluffs.
Bradley, Wm. E., Estherville.
Sandy, Aural A., Harvey.
Johnson, George Monroe, Maquoketa.
Staples, Geo. Allen, Dubuque.
Priestley, Crayke, Des Moines.
Turner, M. L., Des Moines.
Van Marel, G. P., Pella.
Bufkin, E. W., Runnells.

KANSAS.

Jones, Anderson Porter, Hebron.
Jarvis, Louise, Clarksburg.
Depue, Homer B., Parkersburg.

WISCONSIN.

Becker, W. F., Milwaukee.

Medical Organization.

The Ohio Council.

The council of the Ohio State Medical Society met at the Chittenden Hotel, Columbus, November 30. All the members but one were present, and a very admirable spirit of enthusiasm in the work of organizing the profession was displayed. The state was divided up into provisional councilor districts, and a certain number of counties assigned to each councilor. Views as to the best methods of carrying on the work of organization were discussed, and plans of procedure were mapped out. The council organized by the election of Dr. Brooks, F. Beebe of Cincinnati as chairman, and Dr. Thomas Charles Martin of Cleveland as secretary. The following is a list of

the members of the council, with the district which each represents:

FIRST DISTRICT—Counties: Hamilton, Clermont, Brown, Adams, Butler, Warren, Highland, Clinton, Fayette. Councillor, Brooks F. Beebe, Cincinnati.

SECOND DISTRICT—Counties: Preble, Montgomery, Greene, Darke, Miami, Clark, Mercer, Shelby, Champaign. Councillor: Horace Bonner, Dayton.

THIRD DISTRICT—Counties: Van Wert, Auglaize, Logan, Allen, Hardin, Marion, Wyandot, Hancock, Seneca. Councillor, Frank D. Bain, Kenton.

FOURTH DISTRICT—Counties: Paulding, Putnam, Defiance, Henry, Wood, Sandusky, Williams, Fulton, Lucas, Ottawa. Councillor, Julius H. Jacobson, Toledo.

FIFTH DISTRICT—Counties: Erie, Huron, Medina, Cuyahoga, Lorain, Lake, Geauga, Ashtabula, Trumbull. Councillor, Thomas Charles Martin, Cleveland.

SIXTH DISTRICT—Counties: Summit, Portage, Mahoning, Stark, Wayne, Holmes, Ashland, Richland. Councillor, Harry H. Jacobs, Akron.

SEVENTH DISTRICT—Counties: Columbiana, Carroll, Jefferson, Harrison, Belmont, Monroe, Tuscarawas, Coshocton. Councillor, J. C. M. Floyd, Steubenville.

EIGHTH DISTRICT—Counties: Guernsey, Noble, Washington, Muskingum, Morgan, Athens, Licking, Perry. Councillor: Edmund C. Brush, Zanesville.

NINTH DISTRICT—Counties: Hocking, Vinton, Meigs, Pike, Jackson, Gallia, Scioto, Lawrence. Councillor, John E. Sylvester, Wells-ton.

TENTH DISTRICT—Counties: Crawford, Morrow, Knox, Delaware, Madison, Franklin, Union, Pickaway, Fairfield, Ross. Councillor, T. W. Rankin, Columbus.

There are 88 counties in the state, and at present 45 of them have county medical societies. The council feels sure, however, that by the next annual meeting of the Association in May, 1903, there will be a medical society in every county in the state. In view of the willingness shown by every member of the council, it is not too much to expect that this hope will be quite fulfilled. The work of organizing the medical profession of Ohio is in excellent hands.

The Indianapolis Medical Society, the Medical Society of Marion County (Ind.).

The Marion County Medical Society has changed its name to that given above. It will be informally known as the Indianapolis Medical Society.

Charlevoix County (Mich.) Medical Society.

This society was organized at Charlevoix, November 21, with Dr. L. M. Kanagy, Charlevoix, president; Dr. Harmon E. Boice, Boyne, vice-president; Dr. Guy L. Laraway, Boyne Falls, secretary, and Dr. Harry E. Shaver, Boyne, treasurer.

Ohio State Medical Society.

The board of councilors of the Ohio State Medical Society, at a meeting held in Columbus, November 30, empowered the secretary, Dr. P. Max Foshay, Cleveland, to divide the state into districts, for the better organization of the society in all the counties. Each member of the board will have charge of the work in one district. There are now forty-three counties which are not organized.

Carroll County (Tenn.) Medical Society.

The physicians of Carroll County met at Huntingdon, November 20, and reorganized the county society as an integral part of the Medical Society of the State of Tennessee. The following officers were elected: Dr. Joseph W. McCall, Huntingdon, president; Drs. James B. Cox, Huntingdon, and Charles T. Love, McLemoresville, vice-presidents; Dr. William N. Enochs, Huntingdon, secretary, and Dr. Addison McN. Grizzard, Buena Vista, treasurer. Dr. William M. Wright was elected to the House of Delegates of the State Society, with T. C. Love, Hollow Rock, as alternate.

Monroe County (Pa.) Medical Society.

This society, whose object is stated to be "the organization of the medical profession of the county of Monroe by connection with the State Medical Society and the American Medical Association; the promotion of knowledge on subjects connected with the healing art; the advancement of the character and prosperity of those interested in the practice of medicine and the employment of means calculated to render the profession most useful to the public and subservient to the present interests of humanity," was organized at Stroudsburg, November 24. Dr. Nathaniel C. Miller, Stroudsburg, was elected president; Dr. John C. Henry, East Stroudsburg, vice-president; Dr. William E. Gregory, Stroudsburg, secretary, and Dr. Hagerman, Stroudsburg, treasurer.

Van Buren County (Mich.) Medical Society.

On November 7 a meeting of the physicians of Van Buren County was held to organize this society. It was attended by delegates from Decatur, South Haven, Bangor, Mattawan and Lawrence, Drs. George W. Lowry, Hastings, and William H. Haughey, Battle Creek, being present to assist in perfecting the organization as planned by the American Medical Association. Dr. George D. Carnes, South Haven, was elected president; Dr. James Murphy, Bangor, vice-president, and Dr. Norris A. Williams, Bangor, secretary and treasurer.

Societies.

COMING MEETING.

Western Surgical and Gynecological Association, St. Joseph, Mo., Dec. 29 and 30, 1902.

Burlington and Chittenden County (Vt.) Clinical Society.—At the annual meeting of this society in Burlington, November 28, Dr. Harris R. Watkins was elected president; Dr. Bingham H. Stone, vice-president, and Dr. Clarence H. Beecher, secretary and treasurer, all of Burlington.

Iowa County (Iowa) Medical Society.—This society held its annual meeting in Williamsburg, November 21. Dr. William C. Schultze, Marengo, was elected president; Dr. Arnold C. Moon, Williamsburg, vice-president; Dr. Edgar B. Henderson, Marengo, secretary, and Dr. William F. Moershel, Homestead, treasurer.

Keokuk County (Iowa) Medical Society.—This society held its annual meeting at Sigourney, November 25. Dr. William Pfannebecker, Sigourney, was elected president; Dr. Robert H. Payne, Richland, vice-president; Dr. Charles S. Cilley, What Cheer, secretary, and Dr. Leonard B. Oliver, Sigourney, treasurer.

William Pierson Medical Library Association of the Oranges (N. J.).—At the annual meeting of this association, November 28, the following officers were elected: Dr. Thomas W. Harvey, Orange, president; Drs. Richard C. Newton, Montclair, and Joseph C. Young, Newark, vice-presidents; Dr. Richard D. Freeman, South Orange, secretary; Dr. J. Hammond Bradshaw, treasurer, and Dr. Henry A. Pulsford, South Orange, librarian.

Redlands, Riverside, San Bernardino and Pomona Valley (Cal.) Medical Societies.—These societies held a union meeting at Loma Linda, October 22, over which Dr. Frank Garcelon, Pomona, presided, while Dr. Charles C. Browning, Highland, acted as secretary. A committee consisting of Drs. C. von Swalenburg, Riverside, Daniel W. White, San Bernardino, and Elverson E. Major, Redlands, was appointed to consider the organization of a district society.

Northeast Kansas District Medical Society.—This society was organized at Kansas City, Kan., November 24, with 40 members. The counties which form the district are: Atchison, Brown, Doniphan, Douglas, Geary, Jackson, Jefferson, Johnson, Leavenworth, Marshall, Morris, Nemaha, Osage, Pottawatomie, Riley, Shawnee, Wabaunsee and Wyandotte. The purpose of the district organization is to aid the state society in the various phases of its work, but more particularly in the enforcement of the medical practice act. The following officers were elected: Dr. Russell A. Roberts, Kansas City, president; Dr. William E. McVey, Topeka, vice-president; Dr. James Naismith, Lawrence, secretary, and Dr. Clarence C. Goddard, Leavenworth, treasurer. The society will meet in Topeka, Feb. 5, 1903.

NEW YORK ACADEMY OF MEDICINE.

Meeting of the Section on Surgery, Oct. 13, 1902.

Dr. Robert T. Morris in the Chair, protem.

Preoperative Preparation of the Surgeon and His Assistants.

DR. GEORGE R. FOWLER, Brooklyn, read this paper. With regard to disinfection of the hands he said that he preferred the general cleansing by combined mechanical and chemical means. As the nail brush is prone to cause fissures about the nails, it is well to substitute folds of sterile gauze for the nail brush. Metallic nail cleaners for a similar reason are desirable. At one time he endeavored to eliminate this source of infection by having the nails kept very closely trimmed. This

answered well for the purpose intended, but the consequent loss of tactile sense and the inability to pick up small instruments finally caused him to discard this method. He recently found that an excellent method of cleaning the nails was by seesawing with the selva edge of sterile gauze. He elaborated this idea by having constructed a frame of steel spring wire, like the frame of a keyhole saw, and substituting for the saw a small round brush. After thorough scrubbing and disinfection of the hands with alcohol they are usually sterile for a short time, but if placed in warm water for a few minutes microbes will quickly come to the surface.

The author thought rubber gloves undeniably of value, but said their sphere of usefulness was limited to examinations of very septic cases. They are inappropriate for ordinary operative work because of the impairment of tactile sense, the risk of tearing or puncturing them and the catching of the needle in the gloves. The fact that they really poultice the hands, and thus cause numerous microbes to come to the surface of the hands, explains how they may become an added source of danger. He is in the habit of filling the creases in the hand with a solution of potassium permanganate and corrosive sublimate, and one not familiar with the method would be astonished at the coating that dries on the hands after their immersion in this solution. While operating he prefers to dip the hands from time to time in a solution of corrosive sublimate of the strength of 1 to 2000. For this purpose it has been found that a cold solution is much more effective than a hot one.

Dr. Fowler then went on to consider the danger of infection from the uncovered hair, whether of the head or beard. It is only necessary to refer to the frequent presence of dandruff in the scalp, to say nothing of street dust, to see the necessity for covering the head during an operation. He prefers the use of a closely-fitting cap for this purpose. The mouth is also known to be a source of infection, for, while it is probably true that bacteria are not thrown off during quiet expiration, it is entirely different when expiration becomes more forcible or conversation is indulged in. Bacteriologic studies have proved indisputably that under such conditions bacteria are thrown to a considerable distance, which not only shows the need of covering the mouth during operation and refraining from unnecessary conversation, but also suggests the advisability of enjoining silence on all the spectators at surgical clinics.

DISCUSSION.

DR. FREDERICK HOLME WIGGIN approved of the suggestion to use sterile gauze instead of the nail brush. He is accustomed to cleanse the hands and arms by scrubbing for several minutes with a stiff sterile bristle brush and tincture of green soap, and then washing first with alcohol and then with an alcoholic solution of bichlorid of mercury, 1 to 300. A final cleansing is given with sterile water. Only during prolonged operations does he think it necessary to dip the hands into a disinfecting solution, and for this purpose he uses an alcoholic solution of bichlorid, and follows it with sterile salt solution. While he has never used the cap, it is his custom to guard against infecting the wound with perspiration by wearing on the brow a scarf made of several layers of gauze. Conversation during operations should be reduced to the minimum, not only because of possible infection from this source, but because it serves to distract the attention of the operator.

DR. CARL BECK thought it probable that in many instances an infection has been attributed to improperly prepared catgut, when in reality it had arisen from the coming to the surface of bacteria that had been sheltered in the follicles of the skin. The application of tincture of iodine is a good means of controlling skin infection.

DR. MARTIN W. WARE pointed out that cotton gloves should prove superior to rubber ones because they do not tend to macerate the skin of the hands.

DR. JOSEPH WIENER, JR., earnestly recommended rubber gloves, and insisted that those who persisted in their use for two years would find that most of the difficulties of manipulation incident to their use would disappear. After such an experience he would not now think of doing any abdominal operation, any clean or any septic operation without rubber gloves. He now rarely punctures them, and he finds that he

can palpate fully as well with as without them. In the surgical work at the Mt. Sinai Hospital it has been recently discovered that the gloves can be used with greater facility, and that the hands underneath can be kept dry, by free dusting with sterile talcum powder. One of the great advantages of operating with rubber gloves is that should the operator happen to infect the finger by handling pus, the rubber gloves can be almost instantly disinfected, whereas the uncovered hand requires at least fifteen minutes.

DR. ROBERT T. MORRIS remarked that the danger of infection from the puncture of rubber gloves would vary from day to day, depending on the individual powers of resistance at the time. He thought it would be difficult for an inexperienced operator to become expert in palpation with the rubber gloves unless he had previously had the advantage of training in palpation without the use of these gloves. Surgeons who operate with rubber gloves take longer to do a given operation than when they do not use these gloves. The speaker has recently been experimenting with certain sulphite depilatories with a view to securing destruction of skin bacteria, and so far with very encouraging results. As blood serum is known to be germicidal, it is doubtful if it is necessary to dip the hands in a disinfecting solution while operating.

DR. FOWLER, in closing, said he was glad that mention had been made of the danger of infection from perspiration, for he felt sure he had seen one fatal case due to this cause. The application of tincture of iodine to the skin, particularly in emergency, where there was no opportunity for proper preparation of the patient, is an excellent practice which he has used for the past ten years. If rubber gloves are admitted to interfere with the tactile sense, then this objection applied with fifty-fold more force to the use of cotton gloves. He has tried the chlorin method faithfully, and while it seems to satisfactorily sterilize the hands it produces so much irritation of the skin as to make it necessary for many surgeons to avoid it.

Treatment of Diseased Joints by Plaster Strapping.

DR. F. R. COOK described this method, so earnestly advocated by Dr. V. P. Gibney, in 1893, and in many places known by his name. In order to secure full benefit from this treatment it is not enough to merely make a diagnosis of sprain; one should determine what ligaments are involved, whether these have more than one insertion or function, and what special fasciculi are sprained. This information is usually obtained by learning what is the position of the part at the time of the injury, the position of the parts when at rest and when in motion after the injury, and by comparing the amount of pain produced by forcing the parts into all of the extremes of motion of which the joint is capable. It is also well to determine the areas of maximum tenderness and maximum local heat. The strapping acts as a support to the sprained ligaments, as a means of producing counter-irritation or fomentation of the injured part, and produces massage within proper limits. In cases of contusion the strapping is applied with the parts relaxed, and in sprains, with the parts in closer approximation. The method is also applicable to many cases of stiffened joints following fractures or over-immobilization. In strapping the wrist he uses very narrow straps applied in a figure-of-eight. When there is much effusion in the knee-joint, one strap should be carried around the joint at its center, and then the others applied alternately above and below the knee, the straps meeting at the hamstring muscles and diverging. In strapping the shoulder the first straps should be carried from the chest around the shoulder to the back, and then the others applied above and below as in strapping the knee.

BUFFALO ACADEMY OF MEDICINE.

Regular Meeting of the Section on Surgery, held Nov. 3, 1902.

The President, Dr. Herman Hayd, in the Chair.

DR. ROSWELL PARK read a timely paper on "The Physics and Therapeutic Value of the (Roentgen) Cathode and Ultra-Violet Rays, with Certain References to the Electro-Magnetic Theory of Light; with Exhibition of New Instruments for Phototherapy."

Dr. Park referred to the electro-magnetic theory of light, and also to the studies which culminated in the discovery by Roentgen of the cathode rays. These rays are of short vibration, a velocity of 250,000 yards a second, as compared to other light rays, such as the Hertzian rays of longer vibration, and the latter made available by Marconi in his wireless telegraphy apparatus. The source of the cathode rays is electrical discharges in vacuum, and it was in vacuum that Roentgen studied these electrical discharges.

Dr. Park referred to the phenomenon of phosphorescence and to the rare metals radium and uranium, which have great actinic properties. This was illustrated by an experimenter who, carrying one of these metals on his person, suffered a deep and painful slough near the point of contact. These light rays exercise an influence on animal organisms. They also affect plant life, for in their growth plants turn to source of light.

The rays have a bactericidal effect on bacteria, which has been shown by several experimenters, the heat rays being less effective than the chemical rays.

The ultra-violet rays are capable of producing many of the effects of sunlight, i. e., the chemical rays of sunlight on the skin; lesions varying from dermatitis to gangrene can be produced and it seems that this effect is more pronounced in blondes. The actinic effect of light is proportionate to the absorption.

Dr. Park alluded to the influence of light on the variolous process, the deepest scars and marks occurring in such places not protected from the light, head, neck, forearm and hands, to the treatment of smallpox in the middle ages by placing such patients in environments of red light. He also spoke of a photodermatic sense by which certain animals can distinguish by their integument between red rays and blue rays.

Light rays are a bactericidal agent, the question now is as to the depth of penetration. This is proven by the excellent results of the treatment of lupus by the Finsen method. Dr. Park showed the Finsen plano-convex lens, and also the arc-light condenser, which is used for this purpose, and emphasized that the part to be treated should be made bloodless, so as to prevent the blood from absorbing the rays. For this purpose several methods of compression have been devised, such as ice, rock salt, and quartz lenses. A protection should be given to the skin or parts not to be exposed. There are three sources from which the ultra-violet rays may be obtained, (1) sunlight, (2) arc light, (3) condensor spark. The ultra-violet rays and α -rays are bactericidal. During the contact with the rays organisms do not thrive, but removed from their action they will thrive and grow again.

As to the therapeutics of the cathode and ultra-violet rays Dr. Park stated that the kind of lesions which often yield to the action of these rays are lupus, cancer, actinomycosis, furunculosis, etc. The efficacy of action being due to the property of either destroying or preventing growth of germs, this being, according to writers, in part an explanation of the disintegrating effects noted, notably in cancer, which he believes to be parasitic in origin. The rays are better than caustic plasters and pastes, which are not so selective in its action.

A remarkable effect from the use of the rays is the relief of pain seen in deep and superficial cancer. This symptom is often relieved by one or two applications; for this reason it may be used in neuritis and vaginal affections associated with pain.

Dr. Park has submitted 100 cases to the α -rays and ultra-violet rays for treatment. A Finsen plant has been installed and is now ready for use at his clinic at the General Hospital. Some of the cases treated have been successful, in others no improvement was to be seen. The phototherapy is useful for superficial growths and of limited area; it relieves pain; it is adopted to inoperable cases; it relieves the odor of putrefaction in sloughing growths. Burns from its use can be avoided, it is a good supplementary treatment after operations, and does not interfere in its application with a person's business. Dr. Park protects the parts not to be exposed from burns by a layer of putty between layers of oiled silk.

Dr. ELMER G. STARR referred to certain experiments of α -rays on bacterial life. Cultures were placed on colored glass plate and exposed to rays. In red glass bacterial life was fair; in the yellow glass growth was good, equal to sunlight, whereas, in blue glass the growth was checked.

Dr. H. R. GAYLORD stated that the continental physicians still regarded the actinic therapy as being in an experimental stage, but great hopes of ultimate good was entertained. It was used in Breslau in Mikulicz's clinic, and the effects as yet are uncertain. Some cancers are known to disappear.

Dr. MATTHEW D. MANN stated that he had used the α -ray treatment on a number of inoperable cases of cancer at the General Hospital. In one case the effects after three months are marvelous. The case was a woman, 50 years of age, with a cancer of the uterus involving cervix and vagina and inoperable. After a three months' vacation in Europe, the patient being treated meanwhile, he examined her and found her practically well. All cases of cancer are not so successful and Dr. Mann believes that the epitheliomata are the class of cases most benefited. The treatment is now being used on a case of cancer of the external genitals, involving vulva and vagina. It is an epithelioma far past operative interference; another case of epithelioma of cervix is being treated in this manner.

Dr. HERMAN HAYD pleaded for conservatism in the use of α -rays, and stated that in early cases of cancer no time should be wasted in attempting to check growths, but the surgeon's knife is the most certain means. He is somewhat disappointed in the use of the α -rays. On one case of scirrhus cancer it was used after operation, but there was no diminution in growth. It may be that the rays have a selective action for certain forms of cancer, the epitheliomata being those from which the better results can be obtained.

Dr. PARK, in closing, stated that the α -rays should never replace surgical procedure in early cancer cases. It is a good adjuvant and valuable to use after operations.

SANITARY CONFERENCE OF THE AMERICAN REPUBLICS.

Meeting held in Washington, D. C., December 2 to 6, 1902.

Temporary Chairman, Dr. Ulloa of Costa Rica, in the Chair.

This conference, called by the governing board of the International Union of the American Republics in accordance with a resolution adopted at the Second International Conference of the American States, held in the City of Mexico, 1901-02, assembled in Washington, December 2.

Welcome.

The delegates were welcomed to the city by Dr. Walter Wyman, Surgeon-General of the United States Public Health and Marine-Hospital Service, who spoke of the meeting in Mexico last winter as inaugurating a new era in the progress of civilization in the new hemisphere, as it provided for the International Conference on Customs, International Coffee Commission and International Conference on Sanitation and Quarantine. The Secretary of the Treasury and the Assistant Secretary of State extended greetings from their departments. Senor Quesada, minister from Cuba, spoke with much warmth of the part the United States had taken in bringing about better sanitation in Cuba, and paid eloquent tribute to Gen. Leonard Wood, U. S. Army, late military governor of Cuba, and to the late Major Walter Reed for his efforts in ridding the country of yellow fever. Addresses were also made by the Mexican ambassador, Don Manuel de Aspiroz; Major Walter D. McCaw, representing the Army, and Medical Director George P. Bradley, on behalf of the Navy.

Receptions.

A reception to visitors was given at the New Willard, December 3, and they were received by President Roosevelt at noon on December 4.

Committee on Organization.

Dr. Ulloa of Costa Rica was made temporary chairman and appointed as Committee on Organization, Dr. Carlos Finlay, Cuba; Dr. Eduardo Moore, Chile; Dr. H. L. E. Johnson,

Washington, D. C.; Dr. Glendower Owen, and Minister Felipe Carbo, Ecuador. This committee reported the following plan of organization:

Your committee respectfully reports that, to carry out the intent of this Sanitary Conference, there should be:

1. A president, who shall also be the chairman of the executive board known as the International Sanitary Bureau.

2. One vice-president from each republic represented at this conference. The duties of the vice-presidents shall be in the order named, to preside in the absence of the president.

3. A secretary. The duties of the secretary shall be to keep a record of the proceedings of the conference from day to day, with a view to their publication, to be followed by the publication of specially prepared papers relating to the subjects before the conference.

4. An advisory council, to consist of six delegates. The president shall be ex-officio a member of said advisory council. The duties of the advisory council shall be to prepare the program from day to day, to examine and pass upon the papers which it is proposed to be presented before the conference, to consider resolutions that are presented in general meetings and report upon them to the general conference, with recommendation either for their passage or rejection, and to attend to such other matters as may be referred to it.

The committee further nominates the following officers to fill the positions named above, namely: For president, Surgeon-General Walter Wyman, U. S. P. H. and M.-H. Service. For vice-presidents, Dr. Moore, Chile; Dr. Ulloa, Costa Rica; Dr. Guiteras, Cuba; Minister Carbo, Ecuador; Consul General Shernikow, Salvador; Lazo-Arriaga, Guatemala; N. B. Peraza, Honduras; Dr. Liceaga, Mexico; Dr. Roman, Nicaragua; Mr. Stewart, Paraguay; H. L. E. Johnson, United States, and Chargé de Affaires Herrera, Uruguay. For secretary, Dr. Arthur R. Reynolds, Chicago. For members of the advisory council, Dr. Rhett Goode, U. S.; Dr. M. J. Rosenau, U. S.; Dr. Juan Guiteras, Cuba; Dr. E. Liceaga, Mexico; Major Walter D. McCaw, U. S., and Dr. Ulloa, Costa Rica.

The International Sanitary Bureau shall consist of five members, one of whom shall be the president of this conference, the other four members to be nominated to the conference by the advisory council, and the said council shall also recommend to the convention the time and place for the next annual conference.

The report was unanimously adopted by the conference.

(To be continued.)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Hemicrania.

N. F. Howard, in *Atlanta Journal-Record*, employs the following combination in the treatment of migraine:

R. Ammon. muriatis	5iii	90
Tinct. belladonnæ	3i	4
Tinct. hyoseyami	3ii	8
Aq. menth. pip.	3iv	16
Aq. camphoræ q. s. ad	5xvi	480

M. Sig.: One half to one teaspoonful given in sweetened water every two or three hours.

Hemoptysis.

Lemoine, in an abstract in *Amer. Med.*, states that in the hemoptysis occurring at the beginning of tuberculosis, the patient should have absolute rest in bed in a well-aired room and given easily-digested food; revulsion is accomplished by the use of hot foot-baths and purgative enemas. A mustard plaster may be applied to the chest and thighs. Internally the following is given:

R. Pulv. ergotæ	gr. viiss	50
Quininæ sulph.	gr. ivss	30

M. Ft. cachet No. i. Sig.: To be taken in the morning with a bowl of milk.

In the course of tuberculosis, he employs ergotin as follows:

R. Ergotin	gr. 1/6	01
Acidi lactici	gtt. x	05
Aq. destil	3iiss	10

M. Sig.: Four drops may be injected hypodermically at the beginning. If the hemoptysis is persistent, tartar emetic or ipecac must be used.

According to the same periodical iodoform may be given internally in divided doses in the treatment of tuberculosis. The dose is grain 1/6 (.01 gm.) at a time, not exceeding grains 10 (.6) daily. Usually 3 grains (.2) are sufficient. In any case the susceptibility of the patient will govern the dose, which

must be small at first. Iodoform is incompatible with alkalies and calomel. It may be used internally, as follows:

R. Iodoformi	gr. i	06
Guaiacol (crys.)	gr. xlv	3
Olei amygdalæ dulcis	m. iii	20
M. Ft. capsulæ No. iii. Sig.: One three times a day; or:		
R. Iodoformi	gr. xv	1
Olei amygd. dulcis	Oi	500
Spts. cinnamomi	m. xv	1
M. Sig.: One tablespoonful three times a day; or:		
R. Iodoformi	gr. xv	1
Olei morrhue	Oi	500
M. Sig.: One tablespoonful three times a day.		

Externally iodoform is employed in the form of iodoform collodion as follows:

R. Iodoformi	gr. xx-3i	1.30-4
Collodii	3i	30
M. Sig.: Apply locally to the affected parts.		

The foregoing, according to the author, may be employed in all forms of tuberculous suppurations, hydrocele, and exophthalmic goiter. The following combination may be used by injections into the trachea in laryngeal tuberculosis:

R. Iodoformi	gr. xv	1
Olei olivæ (sterile)	3i	30

M. Sig.: To be used in small amounts intratracheally or hypodermically.

Expectorants in Bronchitis.

The following preparations are valuable expectorant mixtures, according to *Pract. Druggist*, which may be employed in the treatment of the different forms of bronchitis where expectorants are indicated:

R. Ammon. carb.	gr. x	65
Tinct. opii camph.	3i	4
Tinct. scillæ	3i	4
Syr. tolutani	3ii	8
Decoct. senegæ q. s. ad	3ii	60

M. Sig.: One teaspoonful every three or four hours; or:

R. Syr. pruni virg.		
Syr. scillæ comp.		
Spts. etheris nitrosi		
Tinct. opii camph., āā	3i	30

M. Sig.: One teaspoonful three or four times a day; or:

R. Olei picis liq.	m. xv	1
Ext. marrubii flu. (horehound)	5ss	2
Olei anise	m. i	06
Spts. frumenti	3i	30
Mellis despumati q. s. ad	3ii	60

M. Sig.: One half to one teaspoonful three or four times a day; or:

R. Syr. senegæ		
Syr. pruni virg.		
Syr. acaciæ, āā	3i	30

M. Sig.: One teaspoonful every four hours for a child.

La Grippe.

The following combination containing heroin is recommended by the *New Orleans Med. and Surg. Jour.* in the treatment of la grippe:

R. Heroin	gr. 3/4	045
Ammon. chloridi	3i	4
Syr. picis liq.	3i	30
Syr. tolutani	3i	30
Syr. pruni virg.	5ss	15

M. Sig.: Two teaspoonfuls every three or four hours.

Salol in Cystitis:

According to the *Jour. de Med. de Paris*, it is advantageous in certain cases to prescribe salol internally in the form of an emulsion. The following preparation is recommended in the treatment of cystitis or gonorrhea instead of the powder:

R. Salol	3i	4
Gum arabic	3i	4
Gum tragacanth.	gr. iii	20
Tinct. tolutani	3iiss	10
Syr. simp.	3i	30
Aq. destil.		

M. Sig.: One teaspoonful three times a day.

Gout.

The following outline of treatment is recommended by Colbeck and Chaplin in the treatment of gout: A mercurial purge in combination with compound jalap powder, colocynth, or rhubarb should constitute the initial treatment, followed after a few hours by a saline aperient. One of the following mixtures should then be prescribed:

R. Potassii bicarb. gr. xx 1|30
Potassii citratis gr. xv 1|
Vini colchici m. xv-xxx 1-2|
Spts. chloroformi m. viii 50
Aque menth. pip. q. s. ad.℥i 30|

M. Ft. mistura. Sig.: Two tablespoonfuls to be taken every four to six hours; or:

R. Vini colchici m. xv-xxx 1-2|
Mag. sulph. 5ss 2|
Mag. carb. gr. x 65
Aq. menth. pip.℥i 30|

M. Sig.: Two tablespoonfuls to be taken every four hours;

or:

R. Ammon. chloridi gr. xv 1|
Potassii citratis gr. xx 1|30
Liq. ammon. cit.℥ii 8|
Spts. etheris nitrosi 3ss 2|
Syr. limonis 5ss 2|
Aq. camphoræ q. s. ad.℥i 30|

M. Ft. mistura. Sig.: Two tablespoonfuls every four to six hours.

The use of local anodyne applications is usually indicated, which may be combined as follows:

R. Linimenti opii
Linimenti chloroformi
Linimenti belladonnæ, āā℥i 30|

M. Ft. linimentum. Sig.: To be applied freely to the inflamed joint; or:

R. Chloralis hydratis gr. ii 12|
Tinct. opii℥ii 8|
Aque q. s. ad.℥i 30|

M. Sig.: To be applied freely to the inflamed joint.

The authors state that after the subsidence of the acute inflammatory process the following ointment may be applied for the relief of the itching and for the promotion of the absorption of the inflammatory products:

R. Chloralis hydratis gr. ii 12|
Potassii iodidi gr. x 65
Lanolini
Adipis, āā 3ss 15|

M. Ft. unguentum. Sig.: To be applied locally to the inflamed joint.

To relieve the pain and insomnia:

R. Pot. bromidi gr. xx 1|30
Tinct. hyoscyami 3ss 2|
Tinct. lupuli℥i 4|
Aque camphoræ q. s. ad.℥i 30|

M. Sig.: Two tablespoonfuls at bedtime.

In chronic gout the following combinations are of service in increasing the elimination:

R. Liquoris arsenicalis m. iii 20|
Potassii iodidi gr. v 35
Syr. sarsap. co. 3ss 15|

Sig.: To be taken at one dose in a wine glass of water three times a day; or:

R. Lithii cit. gr. x 65
Potassii cit. gr. xv 1|
Tinct. colchici m. x 65
Syr. limonis℥i 4|
Aque q. s. ad.℥i 30|

M. Sig.: Two tablespoonfuls to be taken three times a day.

Dilatation of the Stomach.

According to the *Med. Press and Circular*, Professor Robin of Paris does not recognize the existence of dilatation of the stomach except as a consequence of spasm or contracture of the pylorus. However, in rare cases, he states the possibility of such occurrence from atony, or atrophy of the muscular coat. The most characteristic symptoms are epigastric undulation, tension of the same region, pain, regurgitation, eructations and vomiting. If these phenomena come on two hours

after eating, the pylorus is very probably the origin of, the cause. The medical treatment consists in the administration of alkaline solutions to diminish or destroy the hyperacidity of the gastric juice. The following combination is recommended:

R. Sodii sulph. 3i 4|
Sodii bicarb. 3ss 2|
Sodii chloridi gr. xx 1|30
Aq. q. s. ad. Oii 1000|

M. Sig.: Ten ounces to be taken in the morning while fasting, and in three parts, twenty minutes between each. The dose should be increased by two ounces every morning up to half a quart. Among other preparations may be mentioned olive oil, antiseptics, washing out the stomach, purgatives, massage and electricity.

Medicolegal.

Itinerant Doctors' Statute and Dentists.—By Section 700 of the Iowa code the power is given cities and towns to regulate, license and tax "itinerant doctors, itinerant physicians and surgeons," etc. The question was raised in the case of the City of Cherokee vs. Perkins whether a practitioner of dental surgery comes within the definition of itinerant doctor or itinerant physicians and surgeons. In answering this question, the Supreme Court of Iowa says that it has been held that the terms "dentist" and "surgeon" are not interchangeable. Certain it is that the professions are largely separate and distinct from each other. The practice of each is regulated by different chapters of the code, and the legal rights, duties and responsibilities of each are dissimilar in very many respects. If, therefore, the power to license and tax, given to municipalities by statute, is to be confined to "physicians and surgeons," then we note that the language can not be extended to include "dental surgeons." In the opinion of the writer of the Supreme Court's opinion (Bishop, J.), there is every reason for holding the statutes applicable to dentists which could be urged in respect of physicians and surgeons, and the legislature intended to include dentists in the general term "itinerant doctors." The majority of the court, however, hold to the opinion that the provisions of the statute can not be extended so as to include dental surgeons; that, if the legislature had intended to make them subject to the statutory provision, it would have so said in terms; that the expression "itinerant doctor," as found in the statute, is to be classed with the succeeding expression, "itinerant physician and surgeon"; and that both relate to those persons who in some form, or following some school, practice either medicine or surgery, or both.

Act of Insane Person—Committing Suicide.—The Supreme Court of Illinois says, in *Supreme Lodge Mutual Protection vs. Gelbke*, that the act of an insane man is not morally his act, so as to impose moral responsibility or render him amenable to the criminal law, because he is unable to understand his duties and obligations or to form a criminal intent; but the act would be his in fact if it was the result of his volition, although under a delusion. The suicidal act of an insane man is intentional if it is voluntary, with the purpose to take his own life, and with knowledge that such will be the effect of the act. Here there was an agreement in a contract of life insurance which provided for exemption from liability if the death of the insured should be caused by his own suicidal act, whether sane or insane, leaving nothing open, by its terms, except the question whether it was his act, and the Supreme Court holds that the provision rendered the certificate void if the insured committed suicide, unless he was in such a state of mind as to be unconscious of the physical nature of the act which caused his death. Again, it says that the word "suicide" and the words "to die by his own hand," or "by his own act," or "to take his own life," mean the same thing, and each conveys the idea of voluntary, intentional self-destruction. The agreement of the insured in this case was that, if his death should result from his own suicidal act, whether sane or insane, the insurer should not be liable; and, if he took the poison voluntarily, understanding the physical

mature and consequences of his act, with a purpose and intention to cause his death, it made no difference whether he was sane or insane, or whether his intent was rational or irrational. To hold that he must have formed a rational intention would be to make no distinction between an agreement for exemption in the case of committing suicide without any provision as to mental capacity and one like this. A rational intent is one founded on reason, as a faculty of the mind, and opposed to an irrational purpose.

Injury Developing Latent Disease—Delirium Tremens.

—The United States Circuit Court of Appeals, First Circuit, says that it appeared in evidence in Maguire and others vs. Sheehan, a personal injury case brought by the latter party, (1) that prior to his injury the man was in good health; (2) that the delirium tremens which retarded his recovery was caused by the shock of the injury; (3) that the violent acts which delayed the healing of the wound and the knitting of the bones were committed while in a state of delirium. More particularly it appeared in evidence that after the man was taken to the hospital delirium tremens ensued, and that while he was on his back, and should have remained in one position, in order that his leg might knit, this attack of delirium tremens rendered him practically insane, so that he moved about, tore his bandages, and even got out of bed, and that that delayed the knitting of the wound, and had prevented a recovery as complete as otherwise might have been had; in other words, that the man's previous alcoholic condition affected the injuries which resulted from the accident. The parties sued requested that the jury be instructed that, if the man voluntarily put himself in a physical condition where delirium tremens might easily be developed by the shock of an accident, he would be responsible so far as such condition prevented his recovery. They admitted the general rule that, where a personal injury develops a latent disease, the person whose negligence caused the injury is liable to respond in damages for the results of the disease, as well as of the original injury, but they insisted that a distinction should be made between different diseases. It was not denied that the rule applies to malaria, scrofula, rheumatism, erysipelas, cancer and lockjaw, but it was said that it did not apply to ailments which were caused by voluntary and intemperate habits. But the Court of Appeals, holding against the parties sued, says it is not aware of any such exception to the general rule. The difficulties of establishing such an exception are apparent. How far a latent disease, called into activity by an injury, is the result of the habits or voluntary acts of the injured, is a matter of speculation, and necessitates the investigation of difficult and occult questions of cause and effect, which lie outside the scope of judicial inquiry. Beyond general expressions in some decisions, which at most were mere dicta, there was no authority cited by the parties sued which supported their contention. As an almost universal rule, the courts have declined to recognize any such distinction.

Claims Against Estate—Attendance on Tenants.—In the case of Baker vs. Dawson, administrator, an action brought by a physician, the Supreme Court of North Carolina says that it was admitted that the physician rendered medical services within twelve months just prior to the death of the owner of the estate, as follows: (1) To deceased personally, \$347; (2) services to deceased's wife and child, \$84; to tenants of deceased, \$36. The physician sought to have all of the above adjudged to be preferred debts, under section 1416 of the North Carolina code, which places among the sixth class of preferred debts "medical services within the twelve months preceding the decease." This language, however, the Supreme Court says, contemplates only services rendered to the deceased personally; for the indebtedness is given priority if rendered within twelve months prior to his decease, and not within twelve months prior to the decease of his wife, child or tenant. As to them, the physician renders the services like any other creditor, relying on the credit of the person requesting the services that he will pay or can be made to pay. It must be noted that there is no priority, even for medical services rendered the deceased personally, unless he dies. In all other cases the physician's bill is like any other debt. If

the physician wishes to secure such debts he must exact security or proceed to collect by law. When the patient is in his last illness this might be inconvenient or indecent, and, as such illness might extend to twelve months, the law endeavors to secure for the patient medical attention by giving a legal priority for such services, if rendered to the patient within twelve months preceding his decease. But such reason does not apply to services rendered his wife and children, as to which the physician has extended credit, relying on the father or husband or landlord himself paying the debt incurred. There are no words extending the meaning to such debts other than personal services to the debtor, and the language of the statute is restrictive—"For medical services within twelve months prior to the decease,"—meaning the decease of the debtor, not of his wife, child or tenant. The statute, being in derogation of the equity of a pro rata, or proportionate, distribution, should be strictly construed, so as not to confer a priority over other creditors unless clearly called for. And the court says that the trial judge rightly disallowed any priority as to medical services rendered the tenants of the deceased, but erred in rendering judgment therefor, to be paid pro rata with other debts of the deceased, since it was not alleged or proved or admitted that the services were rendered to the tenants at the request of the deceased, and without this the landlord is not liable for such services. It says the judge also erred in adjudging that the bill for medical services rendered the wife and child of the deceased was a preferred debt. He should have rendered judgment for the amount thereof, to be paid *pro rata* with the other unpreferred indebtedness of the deceased.

1. **Brain Surgery.**—Mills believes in operation for brain tumors in carefully chosen cases notwithstanding the large percentage of failures, which he attributes to the errors of localization, lack of exactness in the cranial areas, excessive hemorrhage, contusions of the brain, prolongation of operations and the disturbance of the balance of pressure in the skull. The record as to localization is increasing favorably and the Roentgen rays are material assistants, becoming more and more important. He prefers the Anderson-Makins method of locating the chief craniocerebral landmarks. These writers suggest 1, a median sagittal line, from the glabella to theinion; 2, a frontal line from the midsagittal point to the depression just in front of the ear at the level of the upper border of the meatus; 3, a squamosal line, from the most external point of the external angular process, at the level of the superior border of the orbit, to the junction of the middle and lower thirds of the frontal line, and prolonged for about an inch and a half behind the frontal line. The upper extremity of the central fissure was found by them to lie between the midsagittal point and a point three-fourths of an inch behind it, and the lower extremity of this fissure they located near the squamosal line about three-fourths of an inch in front of its junction with the frontal line. The commencement of the lateral portion of the Sylvian fissure is not at a definite fixed point, but can be usually

found at a point one and a half to two inches behind the angular process, the course of the horizontal portion of this fissure corresponding closely to the squamosal line. The parieto-occipital notch is placed at a point seven-twelfths of the distance from the midsagittal point to theinion. The longitudinal sinus frequently deviates toward the right side in the caudal portion of its course. It is Mills' custom not only to locate the position of the tumor where possible, but also to fix the limits and direction of the osteoplastic flap which it seems most desirable to make. He prefers the Stellwager trephine to the ordinary trephine, the rongeur, the mallet and the chisel, as it saves a great deal of danger from concussion of the brain. For cerebellar tumors he remarks the best operation is one in which the interfering neck muscles are turned back and a good opportunity thus afforded for the scalp-flap and the ordinary trephine. If great care is taken in placing this trephine, the sinuses can be generally avoided and the opening enlarged by the rongeur so that a tumor confined mainly to one lateral lobe of the cerebellum may be removed. Unfortunately these tumors arise generally in the middle lobe and the peduncles and present unsurmountable difficulties. The proximity of the great sinuses adds difficulties to cerebellar operations. He details Keen's opinions in regard to the method of reaching the tumor in these parts. He speaks also with favor of controlling hemorrhage by compression of the carotids as suggested by Crile. In conclusion he reports a case of localized meningitis and gumma of the motor region—diagnosed by clinical study and the Roentgen rays, and successfully operated on. The article is well illustrated.

2. **Tuberculosis.**—Pearson and Gilliland briefly report experiments made by them with bovine and human tuberculosis in the inoculation of cattle. They conclude from their research that they are justified in assuming that after repeated intravenous injections of cultures of tubercle bacilli from human sputum the resistance of young cattle to virulent tubercle bacilli of bovine origin may be increased to such an extent that they are not injured by inoculation with quantities of such cultures which are otherwise capable of causing death or extensive infection. That intravenous injections of much larger quantities of culture of human sputum tubercle bacilli than are necessary to confer a high degree of resistance or immunity on the vaccinated animal, may be employed without danger to that animal. They are experimenting as to the proof of this immunity and the extent to which it is effective in protecting cattle against infection from natural causes and also as to the minimum quantities of culture of non-virulent tubercle bacilli which will serve to produce immunity.

4. **Iodin in Corneal Ulcers.**—Hiers reports a case of the use of iodine in corneal ulcers and remarks that since the beginning of his use of this medication he has treated something over two hundred cases, both those of the phlyctenular variety and those of traumatic origin. He concludes that the special adaptability of iodine, used in the tincture form, is to ulcers of the indolent type. It lessens rather than increases scar tissue. The majority of cases yield readily to its first employment.

7. **Typhoid Fever and Drinking Water.**—The causes of typhoid fever are discussed by Seibert, who notices the seasonal effect on its occurrence as shown by figures of New York City and the Prussian Army, two widely separated localities, with largely the same factors at work. He also gives diagrams showing the typhoid mortality in various cities, some of which are quite striking, especially those of Hamburg, Berlin and other German cities before and after filtration was introduced. It seems evident from this that the chief source of typhoid infection is the pollution of drinking water. In summing up the results of his investigation, he offers the following in substance: All rivers, brooks, creeks and lakes located in populated districts of the United States and Germany have long since become permanently infected by typhoid bacilli. The chief carrier of the typhoid germ is drinking water of the cities and towns, and all cities and towns which are compelled to take their drinking water from such sources are in duty bound to cleanse the same by central sand filtration at the waterworks.

8.—See abstract in *THE JOURNAL* of October 25, p. 1066.

11. **The After-Treatment of Childbirth.**—Hirst thinks that it would be an inestimable blessing to child-bearing women if every physician who laid no claim to special skill in gynecic surgery would have his patients inspected by a specialist shortly after labor and again at the end of the puerperium.

12. **Human and Bovine Tuberculosis.**—De Schweinitz, Dorset and Schroeder report experiments with the inoculation of animals with human tuberculosis bacilli and claim that there can be no doubt that the latter can produce the disease in cattle. The artificial media on which the cultures are made affect the morphologic appearance of the bacilli as well as their virulence.

13. **Cancer.**—Wakefield's conclusions are too lengthy to be reproduced. He holds that the cause of degenerative growths is what he calls sub-katabolism. Cancer is not necessarily a parasitic disease. When bacteria become causative factors they do so acting either as irritants, or by their acid excretions, acting directly and in conjunction with sarcolactic acidity. Cancers are prone to infection, though not more so than other forms of sub-katabolism. He defines this sub-katabolism as a retardation of normal katabolism due to lack of actual alkali and oxidation.

14. **Amputations.**—Estes gives an analysis of a large number of amputations both single and multiple. With the exception of amputations through the thigh above the lower third, there has been no death following amputation in these cases, which is a notable improvement on his former experience as reported by him in 1894. The very high mortality of amputations of the upper third of the thigh is also remarkable. He remarks on the fact that hip amputations, which are usually considered so formidable, showed no greater mortality than those of the upper portion of the thigh. The only difference in the condition and treatment was that in the latter cases the tourniquet is used and in the former the amputation is done by gradual dissection, with careful hemostasis during every step of the operation by means of hemostats. The greater length of time required by this method, he thinks, is not necessarily conducive to fatality and the non-necessity of constriction in a general way is an advantage.

15. **Use and Abuse of Bromids.**—Defendorf calls attention to the danger of the overuse of bromids and their habitual over-employment in insanity. He thinks that if necessary to employ them, they should be alternated with other hypnotics, which is a good rule for all sedative or hypnotic drugs.

16. **Myxedema.**—Loveland reports two cases and calls attention to certain points of diagnosis. Both patients lacked the commonly seen skin pigmentation. In the first case a nervous shock seemed to be very obviously the cause; in the second there was a history of glandular inflammation in the throat, in which the thyroid was probably involved. The slow and weak pulse was also noted. He calls particular attention to the character of the voice in these cases which can not be accurately described, but must be heard to be appreciated. Both cases were improved by thyroid treatment.

19. **Hyoscin in Treatment of the Morphin Habit.**—The case reported by Rosenberger was treated by the total withdrawal of morphin and large doses of hyoscin at short intervals; 1/100 of a grain being given every hour for four and one-half days at one period. The patient was apparently delirious or semi-delirious for several days. The hyoscin was kept up for fourteen days altogether, during which time the patient had taken 1 and 22/25 gr., followed later by 1/30 gr. of nitrate of strychnia four times daily. The favorable results of the case impressed the author with the value of this form of treatment.

20. **Infant Feeding.**—The indications for the variation of sugar, fats and proteids in infant feeding are given by Abrams as follows: 1. If the bowel movements are curdy we may take it as an indication of an excess of proteids. 2. Sour vomiting indicates too much fat. 3. Stools that are very watery but without curds may depend on too much sugar or too much fat. 4. Vomiting of hard curdy masses may indicate too much pro-

teids. 5. Should the child seem to do well on the mixture in every way except that it does not gain in weight, then the sugar may be too low. 6. Vomiting may mean that the child has eaten too much. These rules are not absolute, but they are sufficiently correct for a guide. He sums up by concluding that:

1. Breast milk is the best infant food.

2. That no artificial food can or should be trusted which does not contain the essentials of breast milk, viz.: fat, proteids and sugar.

3. That the elements named are to be found only in milk, cow's milk being the only one available for general use.

4. That cow's milk must be modified because it does not contain the same proportions of the elements named.

21. **Appendicitis.**—Blackwell notices the frequency of appendicitis and the importance of its diagnosis. The recognition of the fact that one-half the cases recover under medical treatment should, in a measure, lead to deliberation and restriction within legitimate bounds of operative procedures.

22. **Albargin.**—This substance, which is said to be composed of nitrate of silver in gelatose, containing 15 per cent. of the silver nitrate, has been employed by Klotz in gonorrhea with very good results. He finds that in small doses of 1 to 2/1000 it is non-irritating, but he would not assume responsibility for the effects of strong solutions of one-half to 1 and 2 per cent., though he has never seen trouble from it himself. He is inclined to consider the drug as coming near to Neisser's idea of an ideal gonorrheal gonococcicide and that it deserves a trial.

23. **Alcoholic Heredity in Children.**—Crothers notices the condition in children characterized by feeble vitality and degeneration of the cell and nerve function and the special affinity of the brain centers for stimulants and narcotics as the result of heredity in children of alcoholic parentage. He gives the general principles which should govern the treatment of such cases, absolute abstinence from all alcoholics and narcotics and from meats on account of their stimulating character. A hygienic treatment consisting in everything that can build up the system and avoid brain and nerve stimulation is required, with careful guarding against all extremes.

24. **Intussusception.**—The chief sign for early diagnosis is given by Ruber as the characteristic colic. Next is noticed more or less change in the facies of the child; vomiting sets in, followed by the escape from the rectum of blood or bloody mucus, and more or less collapse. A swelling or rather fulness is noted in the right iliac fossa, particularly during the colicky attacks. This symptom-complex is characteristic, and if the possible occurrence of intussusception is kept in mind an early diagnosis can be made without difficulty.

25.—See abstract in *THE JOURNAL* of November 8, p. 1205.

26. **Heart Wounds.**—Hill reports an interesting case of wounds of the left ventricle, three-eighths of an inch in extent, causing severe hemorrhage, treated with catgut suture and ending in recovery. He gives an analytic table of the cases that have been reported, and concludes from his own experience and a review of the cases tabulated, that any operation which reduces the mortality of a given injury from 90 to about 63 per cent. is entitled to a permanent place in surgery, and that every wound of the heart should be operated on immediately. In any case where there is a suspicion of a wound of the heart exploratory operation should be performed at once. Unless the patient is unconscious and the corneal reflex abolished, an anesthetic should be given, preferably chloroform. Struggling is liable to produce a detachment of the clot and renew the hemorrhage. Never probe the wound, as serious injury may be inflicted on the myocardium. Rotter's operation renders access to the heart extremely easy, and should be generally adopted. Steady the heart before attempting to suture it, either by carrying the hand under the organ and lifting it up, or, if the hole is large enough, introduce the little finger as did Parozzani, which will serve the double purpose of stopping the bleeding and facilitating the passage of the stitches. Catgut sutures should be used, as wounds of the heart heal in a remarkably short time, and they should be interrupted, introduced and tied during diastole, and not involve the endocardium. As few as possible should be passed, preventing leakage, as they cause a degeneration of the muscular fiber, with its tendency to dila-

tation and rupture. In cleansing the pericardium it should be sponged out, and no fluid poured into the sac. Perfect cleanliness should be secured excepting in cases where instant intervention is required. The wound in the pericardium should be closed, and if symptoms of compression appear, reopened and drained.

27. **Hyoscin in Drug Habits.**—Russell reports a case treated by hypodermics of hyoscin at comparatively long intervals, not one of the cases where they were given every hour, such as have been reported. The results seemed to be good.

28. **Perforation of Meckel's Diverticulum.**—Halstead reports two cases and discusses the literature, finding only two similar cases of typhoid perforation. He remarks that in none of the reported cases was the cause of the symptoms recognized before the abdomen was opened.

29. **The Normal Appendix.**—From their observations, Monks and Blake deduce the following conclusions:

1. **Length.**—The average length of the appendix in men, women and children, indiscriminately, is 7.9 cm. (3 inches); the extremes being 1 cm. (a little over 1-3 of an inch) and 24 cm. (a little over 9 1-3 inches).

There is apparently no relation between the length of the body, the sex or age of the subject, and the length of the appendix, except that children are apt to have an appendix proportionately longer than adults.

2. **Mesentery.**—Fully one-half of all appendices have a mesentery (meso-appendix) which reaches nearly or quite to the tip. Of the other half by far the greatest proportion have mesenteries reaching as far as the middle point of the appendix or beyond it. Occasionally an appendix has no mesentery at all.

3. **Position (or Direction).**—The commonest position for the appendix is "down and in" (that is, toward the pelvis), the appendix very frequently hanging over the brim. The second commonest position is "behind the cecum." The third is "down" and the fourth is "in." The appendix is in one of these four positions in about three-quarters of all cases.

30. **Rupture of the Intestine.**—Six cases are reported here, including four recoveries. In one there was no evidence of direct contusion of the abdominal wall. It seemed to be a case of rupture from within and the results of a sort of contrecoup. The most important factor in these cases is the length of time allowed to elapse between the accident and the hour of operation. Beyond the fourth or fifth hour every hour of delay adds greatly to the danger of a fatal issue.

31. **Pseudo-Pernicious Anemia.**—The cases reported by Morse which justified the clinical diagnosis of pernicious anemia were found due to malaria and to hemorrhages from hemorrhoids and the bladder. He calls attention to the importance of looking for slight and frequent hemorrhages as a cause of this condition.

33. **Gastric Tetany.**—The chief part of Strong's paper is a critical discussion of the literature and the opinions in regard to the subject. He summarizes as follows:

1. The condition is a symptom-complex, indicative of an increased nervous irritability, probably central in location.

2. The muscular spasm is a reflex phenomenon set loose by some mechanical stimulation, as vomiting or lavage, with possibly a direct action, in the case of pressure and electrical stimulation of peripheral nerve trunks. The spasm, however, can not be produced without the antecedent nervous irritability.

3. The chief factor in the diagnosis is the muscular spasm itself, affecting the arms in a characteristic manner. Other symptoms, while usually present, are not of absolute diagnostic value.

4. The etiology of the underlying nervous hyperirritability is unknown. The theory of intoxication is the only one adequate to explain the condition.

34. **Circumcision.**—The method here described and illustrated by Krouse consists in perforating the prepuce over the corona and cutting down from the top on a grooved director from this perforation to another similar one on the side of the frenum, repeating this on the other side and finishing the incision below. He obtains the best results from this method.

37. **Drainage in Abdominal Section.**—The conditions requiring drainage are summed by McGuire as follows: 1. In uncontrollable bleeding, as after enucleation of an intraligamentous cyst. 2. When profuse serous transudation is probable, as after the removal of a large adherent ovarian tumor. 3. When localized collections of pus are found, as in case of an appendiceal abscess. 4. When acute general peritonitis exists. 5. When protective adhesions are desired, as in drainage of the gall-bladder. 6. When secondary infection is feared, as in some cases of intestinal lesions. He describes the different forms of drains, including his own, a soft gum tube surrounded by numerous strands of cordine in a casing of thin

rubber tube. The inner tube projects beyond the cordine and the latter beyond the outer tube.

39. **Curettement of the Uterus.**—The rules formulated by Johnston are: 1. Have a distinct and sufficient reason for the procedure. 2. Observe a most scrupulously perfect technic as to asepticism. 3. Dilate the cervix slowly and thoroughly under anesthesia. 4. Apply the curette with great gentleness, but completely and thoroughly removing all diseased tissues. 5. Conduct the subsequent dressings and after-treatment with the same rigid care that appertains to other surgical operations.

40. **Puerperal Appendicitis.**—The following are the conclusions of Ricketts' article:

1. That puerperal appendicitis is as distinct as salpingitis, with or without pus. 2. It can be diagnosed and differentiated from a puerperal septicemia due to other causes. 3. That many cases of peritonitis arise from the infected appendix, and not from the results of pregnancy and child-birth. 4. The reason that puerperal appendicitis has been overlooked explains why it is claimed that appendicitis is more frequent among males than females. 5. With puerperal appendicitis recognized the disease will be found as often among women as among men.

41. **Gonococcal Reinfections from the Seminal Vesicles.**—According to Townsend, spermato-cystitis is a frequently overlooked complication of gonorrhea and a prolific cause of recurrent gonorrhea. A differential diagnosis from acute gonorrhea can be made and is essential to correct treatment. Clear urine may often be seen while gonococci abound in the seminal vesicles. Especially careful examination and observation of these organs should be made before assurance of cure and before consent to marriage is given.

43. **Gant's Femoral Osteotomy.**—This operation is recommended by Shands as deserving more general adoption. It consists in a subtrochanteric osteotomy, and he gives the details of the technic as follows:

The field of operation having been rendered aseptic, a sand bag is placed between the thighs and pressed firmly against the perineum by an assistant, who at the same time holds the patient on the side; the osteotome is introduced in the long axis of the femur about a finger's breadth below the trochanter minor and by manual force is forced down to the bone. No scalpel is used. The osteotome should be sharp enough to cut its own way through the soft structures with light pressure. As soon as the bone is reached, one gentle tap of the mallet will cut through the periosteum; the instrument is then turned in the transverse axis of the bone under the periosteum, which makes the operation subperiosteal as well as subcutaneous. A few blows with a mallet will force the osteotome into the medullary cavity; the instrument is then partly withdrawn and tilted so that a few more blows from the mallet will divide the upper fragment of the bone; and after the same has been done for the lower fragment, the fracture can be easily completed by manual force. Great care should be had not to use sufficient force to break up the adhesion of the head of the femur to the ilium, or to splinter the shaft of the femur at the seat of the operation. The only local dressing used is a piece of gauze and a small strip of adhesive plaster to hold it in place. The limb is put up in a plaster of Paris spica extending from the nipples to the toes, after bringing the limb into the best possible position obtainable.

When the limb is flexed to a right angle on the thigh, and often when not so much distorted, the muscles inserted about the anterior posterior spinous process and the fascia lata will have to be divided before the limb can be brought into its proper position; this can be done subcutaneously and adds nothing to the gravity of the operation.

47. **Appendicitis.**—Randall considers that appendicitis is due to previous bowel trouble. He notices the frequency of appendicitis in returned soldiers from the Philippines, while they suffered very little there from it. As long as the flux continued the appendiceal trouble did not seem to develop, but it is a later consequence.

49. **Hypnotism.**—Henderson thinks that hypnotism is of value in treating the insane, though it is very uncertain. It has, however, a tendency to increase delusions, and it should be used only in selected cases. He considers it specially indicated in the treatment of so-called "semi-conscious pain," which he illustrates by cases, while its employment would be wrong in some forms of hysteria. He insists on the importance of differentiating hysterical paraplegia from actual organic disease in these subjects, as hypnotism is not good for this special hysterical symptom. In conclusion he remarks: "Always have the full consent of the patient and have some responsible friend or relative of the patient present. Do not try experiments, but use it legitimately."

52.—Ibid.

56. Epilepsy.—Doran, who is first assistant at the Craig Colony, reviews the results of operative interference in epilepsy from the data in the literature and his personal experience. He classifies the operations under three headings: 1. Those undertaken with the expectation of removing the source of irritation in the brain. 2. Those done on the theory that the disease is caused by some abnormality of intracranial pressure or circulation. 3. Those promoted by a belief in the reflex origin of epilepsy. In the first group various operations such as trephining for cysts and tumors in the brain are included. In the second belong tapping and drainage of the cerebral ventricles, ligature of one or both vertebral arteries, etc., while in the third class are a great variety of procedures, such as cutting eye muscles and all the numerous operations for eye-strain, removal of nasal and other growths, division of the sympathetic, excision of the cicatrices, castration, circumcision, oophorectomy, etc. Many of these operations are no longer in use, though he does not condemn them entirely. Reflex epilepsy is undoubtedly rare, yet all possible sources of reflex irritation should be sought for and treated, and the patient should have the benefit of the doubt if there is a possibility of the operation being helpful, and if it is not too dangerous. He does not feel much enthusiasm from the results in his experience. Considerable operative work has been done at Craig Colony with results that have not been altogether satisfactory. The experience of recent years has done much to fix the limitations of the operation of trephining. Of the 29 cases trephined at the Colony either before or after admission, the result in those trephined before can be estimated by the fact of their admission, and these include 24 cases. Of 5 cases trephined at the Colony, 2 were done too recently to be mentioned. The records of the other 3 are given, and in no case did they show a cure, though there was a temporary or partial benefit in 2. In one there appears to have been little benefit from the operation. These were all reoperations, having been previously operated on before admission, and they were all kept under medical treatment after operation. To this is attributed the partial good results in at least one case. These results are not encouraging and show the futility of late operations. The earlier after the onset of epileptic symptoms the better the chances. Cases should be selected with great care and studied from both the medical and surgical standpoints. Partial epilepsy is not altogether an indication, and the question of heredity should be considered. The second operation specially noted is that of oophorectomy. Doran says that when everything else has been tried, and the patient is becoming worse morally, mentally and physically, and especially when erotic tendencies are present, which make it dangerous to allow her any liberty, and the attacks are worse and occur more frequently at the menstrual period, and still more so when there is ovarian disease which would justify operation in a non-epileptic patient, there certainly can be no harm in removing the ovaries. Four cases are reported. In one there seemed to be good results, but there had been long periods of freedom from the disease before, and there was a source of irritation in the diseased organs which justified operation. In the others there was improvement, but it is too early yet to judge of the results. He thinks that many so-called cures resulting from operation have been reported too soon, though if the patient goes three years without convulsion, we may perhaps consider it a recovery. Too much dependence must not be placed on the operation itself. The patient's general health should be watched, the diet regulated, and the bromid treatment used if it is possible to benefit the condition. It is of special importance also that the patients should abstain from alcohol, their habits be carefully regulated and that they should be kept from all forms of excess and all mental and physical overexertion.

58. Cerebral Rheumatism.—The value of cold baths in cerebral rheumatism is discussed by Shellenberg, who thinks that even with excessive hyperpyrexia and cerebral complications there has been a high mortality, and it is possible that by resorting to the bath the fatal issue may be avoided.

67. Chronic Nephritis.—The nervous symptoms of chronic Bright's disease are noticed by Lloyd, who divides them into those which manifest themselves, first, in the regional, and

second, in the general way. By regional he means affections of the cerebrum; by general, those that impair the general tone or the whole nervous system so as to constitute a symptom-complex that is not unlike the general state known as neurasthenia. Of the former he remarks that they are manifested almost exclusively in the brain. There are few, if any, spinal or peripheral affections caused by derangement of the kidneys, and this may be taken as a general law. The one exception is in the optic nerve, but it is practically a prolongation of the cerebral axis. Headache is a symptom of very grave importance. He does not say that it is common, but it is frequently overlooked. There is no other symptom which should do more to teach us the rule that every patient should have the benefit of a urine analysis. There is only one type of headache more obscure and intractable; that is the morning headache of gout. Distinction between the two is sometimes difficult. The headache of Bright's disease, however, is rarely so isolated a symptom. There is generally some associated failure of health, appetite and strength and generally a neurasthenic state. There may be nausea and vomiting with it so as to simulate migraine, as may also the eye symptoms. Only a very careless observer, however, would confound the two. Some authors refer to deafness, with associated giddiness, as being caused by Bright's disease and seem to think the auditory nerves are probably affected, but this is largely speculative. Among the most striking regional symptoms, which are often preceded by headache and amblyopia, are uremic convulsions as well as minor convulsions and stupor. There is nothing absolutely distinctive about the convulsion and coma of uremia and the diagnosis must be made by the process of exclusion and history of the case, and examination of the urine, and even then some of these factors are so uncertain that an accurate diagnosis is often difficult. He gives illustrative cases and shows how a physician may be discredited by his diagnosis. The brain symptoms may closely resemble those of organic disease within the cranium, and the closest study may be required. We must remember, however, that albumin and tube casts do not exclude tumor. He refers to Dr. Riesman's paper at Saratoga on uremic aphasia (*THE JOURNAL*, October 11), and accounts for such on the theory of a vascular lesion. A predisposing focal lesion in the brain and uremic poisoning in the blood in addition may act as a paralyzant on the starved tissue. In conclusion he calls attention to the curious hysterical and neurasthenic symptoms which sometimes occur, especially in the early course of Bright's disease. He thinks that such patients are sometimes given rest treatment, as being purely neurotic. The only safe rule is to make a clinical examination of the urine.

68. Ocular Manifestations in Nephritis.—De Schweinitz reviews the various forms, first enumerating them, including complete blindness, the various types of retinitis and neuroretinitis, alterations in the caliber and relation of the retinal vessels owing to sclerotic changes in their walls, with or without hemorrhages and exudates in the retina, alterations in the uveal tract, some varieties of cataract, paresis and paralysis of the ocular muscles, especially the superior oblique and the external rectus, and recurring subconjunctival hemorrhages. These are discussed at length. He thinks fully 25 per cent. of the cases of chronic Bright's disease in general hospitals are affected by various forms of retinitis. The prognosis as regards life is bad with these conditions, and remarks are made as to the close resemblance between cerebral tumor symptoms and those of Bright's disease in certain cases. He also thinks the recurring subconjunctival hemorrhages ought to receive consideration among the ocular signs of nephritis.

70. Gastropnoia.—While the etiology of this and associated conditions is difficult to explain, Francine recognizes two sets of causes: the predisposing and the exciting. The former are congenital weakness and hereditary predisposition. Among the most frequent of the latter are tight-lacing, rapid emaciation, disease of the abdominal integuments, or anything that constricts the thorax or enlarges the capacity of the abdomen. Enteroptosis, or more specifically coloptosis, is generally agreed to be the primary factor physiologically and to precede the gastropnoia. The kidney and liver follow later. In other

words, there is a vicious circle in which the abdomen and hepatic flexure are first involved and secondarily the stomach and kidney. Late investigations seem to point to the liver as the primary factor in many cases of enteroptosis, and there is little doubt that it would be impossible for the intestine to remain long in place after dislocation of the liver. Chlorosis and neurasthenia should be looked on as manifestations of a common underlying cause, supposedly constitutional weakness or faulty development, rather than as direct causative factors.

76.—See also title 41, above.

78.—*Ibid.*, 40, above.

79.—*Ibid.*, 39, above.

77. **Intra-Pelvic Drainage in Males.**—Taylor has made dissections to determine whether the peritoneal pouch in the male pelvis can be drained to advantage similar to that of the female. He finds the rectum loosely attached behind, but more closely so in front, by the prostatic peritoneal aponeurosis, connected with the recto-vesical fascia. It, however, allows separation of the rectum from the prostate and bladder. The anterior wall of the rectum can be separated by blunt dissection and reflected toward the sacrum. Recalling the fact that the recto-vesical pouch is the most dependent point of the peritoneal sac, he reports a case where, through an unfortunate error in dressing, the patient was lost, though the operation was a success. A perineal incision was made and the rectum separated by simply pushing the finger in the perineal wound up to the recto-vesical pouch—a blunt dissection with the finger. He thinks this plan, however, in spite of the misfortune in this case, has a decided advantage over any other plan when dependent pelvic and abdominal drainage is required. With the peritoneal cavity opened and assisted by one hand in the pelvis above, this procedure is as easy as opening the Douglas cul-de-sac through the vagina. He thinks drainage can often be effected without opening the abdomen above, and in some cases may tide the patient over a crisis just as is done by intravaginal drainage. If, however, the recto-vesical pouch is not distended, he doubts whether it would be an easy matter to puncture it as it would easily be pushed inward by the finger or the scissors. If protection to the urethra is thought essential, it can be secured by passing a sound into the bladder. A more probable accident, he thinks, would be a puncture of the rectal wall, but this would be very improbable because of the loose attachment and the added safeguard of a finger as a guide in the rectum.

80.—See abstract in *THE JOURNAL* of November 8, p. 1205.

83. **Peritoneal Adhesions.**—The importance of preserving intact the peritoneal endothelium is insisted on by Morris, who criticises long operation, the use of rubber gloves, etc., as being the causation of adhesions from injury to the endothelium. He points out the dangers of adhesions in producing angulation of the bowel, bloating, involvement of the sensory nerves, and therefore the production of pain, etc. The remedy which he notices is covering the denuded surfaces with omentum according to Senn's method in selected cases, but an extension and amplification of this principle seems to be offered in the use of Cargile membrane for covering denuded surfaces of the peritoneum.

84.—See abstract in *THE JOURNAL* of October 18, p. 1001.

91.—See editorial in *THE JOURNAL* of November 22, p. 1327.

93. **Roentgen Ray in Obstetrics.**—Cooke finds that the value of the α -ray for studying the dimensions of the pelvis is practically lost on account of the difficulties of its use, and at best it is probably not so reliable as mensuration and palpation performed by a skilled observer. In the study of the gravid uterus the results are wholly unsatisfactory when compared with those obtained by the ordinary recognized methods of examination. For diagnosing certain forms of ectopic gestation fairly reliable presumptive evidence may possibly be secured, but more positive methods will be needed before it can be accepted. Advanced pseudocyesis could doubtless be detected by the use of the rays, but a little chloroform will accomplish the same results more easily. In suspected twin preg-

nancies, where diagnosis can not be made with certainty, the α -ray may have a distinct diagnostic value and would doubtless be of service.

95. **Phthisis Pulmonalis.**—Crismond claims good results from the following treatment: Injection under aseptic precautions of cod liver oil containing bromin and iodine, beginning with 15 minims, and increasing 5 minims each day until 60 minims are reached, keeping this up as long as the patient is under treatment, that is, from two to three months. He also anoints the patient every night after a cabinet bath, with two ounces of perfumed cod liver oil. The patient's nasal cavities are thoroughly sprayed with an antiseptic fluid every morning and his lungs and respiratory organs are filled with nebulized medicine. This, with the open-air treatment and breathing exercises, gives what he considers good results.

103. **Squint.**—Black describes his apparatus consisting of a wooden base supporting an upright. At right angles to the center and top of this upright is attached an arm which can be turned to the right or left at the center of the upright; on the back of this arm a scale of degrees is marked. The light is a long miniature electric lamp that can be flashed on and off with a push button. On the arm is a small marker to attract the patient's attention. The scale is made by extending the radii through the arc of the circle to the arm which forms the tangent, the radius being 60 cm., or the distance of the patient's eyes from the light.

To measure the deviation, the patient is placed in front of the apparatus with the elbows resting on the table. The distance of the eyes being regulated by a cord to which is attached a ring which is held on the little finger at the orbital margin; the light being flashed on will at once attract their attention, the position of the corneal reflex is noted in the fixing eye and the patient directed to look at the marker, which is moved to or from the upright until the reflex of the deviating eye is relatively in the same position as it was in the fixing eye when looking at the light; by directing the patient to look first at the light and then at the marker, the reflex can be located exactly in the deviating eye and the degree read off on the back of the arm opposite the position of the marker. With small children or babies, the mother or nurse holds them on the lap with the child's head between the hands; a match is lighted and held over the marker, at which the baby will naturally look; this is moved back and forth, the electric light being flashed on and off from time to time until the corneal reflex is in relatively the same position in the deviating eye. The light can be flashed on and off so quickly that the child can not have time to change its gaze from the lighted match to the electric light.

104. **Correction of Myopia.**—Friedmann formerly used to consider full correction dangerous, but he thinks if it does no harm it has great advantages by giving the myope the natural conditions of accommodation and convergence. He gives a letter from Knapp, who considers it the correct treatment in good vision with no dangerous fundus changes.

105. **Correction of Myopia.**—Jackson gives statistics showing the advantages, as he considers them, of full correction. He knows of no statistics so extensive as these which can be said to point to any different conclusion. There are exceptions to the rule of full correction, but they do not detract from its importance.

110.—See abstract in *THE JOURNAL* of October 4, p. 855.

111.—*Ibid.*

113. **Epidermolysis Bullosa Hereditaria.**—Wende reports a case of this condition closely resembling in its type the so-called dystrophic variety, and having some unique features. He thinks in the recognition of this group we should consider the chief symptom involved, that of the bulla formation, not forgetting the fact that epidermolysis bullosa, regardless of any subsequent alteration that may appear in any particular case, should always be so classified. He thinks the general etiologic factors at work in these cases are possibly a hereditary or congenital lack of resistance in the skin in connection with poor trophic innervation. There is probably an increased irritability of afferent nerve endings in the skin, by means of which irritation, which ordinarily would have no effect, causes a local vaso-dilator influence through the vasomotor system.

114. **Exfoliative Dermatitis.**—Bowen reports four cases, each of a different type, the first of recurrent desquamative scarlatiniform erythema, which has been abundantly described. The second one was of the type of dermatitis exfoliativa of Wilson. Not so very distinct from this form or type he notices a third case, that of the common secondary exfoliative erythema

developing from psoriasis, eczema, lichen planus, etc., or caused by drugs. Of these he has never known one to have a fatal termination. The last was a case of pityriasis rubra ending fatally and uncomplicated with any tuberculous symptoms.

123.—See editorial in *THE JOURNAL* of November 22, p. 1327.

124. *Chorditis Cantorum*.—Singers' nodes, according to Miller, are due to overstrain of the chords. He illustrates his theory by anatomic descriptions. He finds quick restoration in every case where the proper mental picture of the vocal effort is given to the patient, with a consequent relaxation of the overexerted parts and strengthening of the normal voice supports. The details of his paper are too elaborate to be given here.

125. *Benign Tumors of the Naso-Pharynx*.—The various types of these growths are described by Quinlan with their treatment. He thinks that every case should be treated individually. The forceps which has been in general vogue in the past is now being distrusted on account of the accidents which have followed its use. Experience has been somewhat similar with the hot snare. We do not read of so many cures by the galvanocautic loop as in former years. He is inclined to think the cold snare the best procedure in the vast majority of selected cases. Certain growths, of course, are beyond its reach, but no rules can be laid down in this respect. The typical fibromata can often be removed, while growths which are intrinsically much less formidable are sometimes unapproachable by this means. A certain minority of nasopharyngeal growths can only be removed by the most radical procedures, such as splitting the intervening hard and soft parts and suturing the flaps after the extirpation of the tumors.

127. *Laryngeal Stenosis*.—Two cases of this condition are reported by Clark. In the first case he dilated the stenosis with a female urethral sound, which he thinks is a very admirable means in such cases. In the second case the repeated contraction of the cicatricial tissue rendered the use of the intubation tube almost imperative for a long time, and he almost despaired of getting along without it. He finally succeeded by passing tubes of different sizes and left the patient in a comparatively comfortable position as regards breathing, though the vocal function was impaired.

131.—See editorial in *THE JOURNAL* of November 22, p. 1327.

135. *Cancer*.—The parasitic theory of cancer is discussed by Robin, who is not willing to go quite as far as the Harvard Commission in their conclusions. He is willing to admit that protozoön-like types are found in cancer, but this does not establish their interrelation. It is readily conceived how parasites may contaminate tumors which are exposed to the external air, and exist as a secondary invasion and perhaps accelerate the growth and cachexia.

136. *Cancer of the Rectum*.—The various methods for operation on cancer of the rectum are described by Gant, who gives in detail the technic. He thinks in certain cases vaginal proctectomy should take precedence over the Kocher and Kraske operation, as in all cases in which the growth is so situated it can be removed from the front.

137. *Roentgen Rays in Cancer*.—From clinical experience up to the present time, Leonard considers the following conclusions justified: 1. We have a more potent remedial agent than any other in the Roentgen rays, but they can not be considered as a cure-all, and should not be employed to supersede operation, but to supplement it. The best interests of the patient will be served by early diagnosis, early radical removal by surgical intervention, and subsequent thorough treatment of the infected area by the Roentgen method. Inoperable cases and superficial growths not liable to produce death or give rise to metastases, and also recurrences, may reasonably be submitted to Roentgen treatment previous to operation. It should only be employed by practitioners qualified by education and experience to judge of the therapeutic effects and estimate the proper dosage. We need wider clinical experience before we can have an effective application of this remedy in deep-seated malignant disease.

138. *Mercuric Cataphoresis in Cancer*.—Massey describes his method, which has been published elsewhere, consisting in injection of mercury in the form of ordinary quicksilver into the growth or held within it in union, with a solid electrode of zinc, and being made the anode of the current is attacked by the electrolytic process and the resulting nascent compound, a soluble oxychlorid of mercury and zinc, is diffused throughout the growth rapidly, the patient being under a local or general anesthetic. The result is that the radiating chemicals unite with the protoplasm of the cells and other elements of the growth, producing a rapidly enlarging area of necrosis, which is most effective in the degenerating tissues. The opposite pole being on a distant part of the body, the lines of diffusion will tend to follow the so-called roots of the cancer to their extremities. He finds a current strength of 500 to 800 milliamperes, more or less, applied for sixty minutes, most effective, and considers that the method has decided advantages over the knife. Its disadvantages are the cost of the paraphernalia and the necessity of a knowledge of medical electrophysics in the operator. It also has disadvantages as compared with the x-ray in requiring anesthesia and of producing a wound at the site of the growth, but this is readily curable, differing in this respect from the x-ray wounds. The knife is still preferable in operative growths of internal organs capable of removal, and highly malignant sarcomas of the extremities in which it is possible to amputate the limb far above the site of the disease, but the employment of cataphoresis is better where it is inadvisable to remove extensive contiguous tracts, which can also be sterilized by this method. The x-ray should be used in external growths too extensive for quick eradication by mercuric cataphoresis, in inoperable growths within the chest or abdomen and in general carcinomatosis where other methods fail. He has employed the method in 60 unselected cases where it was begun generally as a forlorn hope, and has had 18 cures, 7 of them having passed the three-year limit.

144.—See editorial in *THE JOURNAL* of November 22, p. 1327.

149. *Treatment of Pneumonia*.—The principal points made by Thomas are the reduction of blood pressure and fever during the first forty-eight hours if possible. In the second stage where danger begins, he would use external applications so far as possible in preference to morphine, etc., for the pain, expectorants if indicated, conserving the patient's strength with good nutritious diet and the best hygienic surroundings and especially look for and guard against heart failure. The larger part of his article is an argument for heart stimulation by strychnia, nitroglycerin, etc.

154.—See editorial in *THE JOURNAL* of November 22, p. 1327.

159.—See abstract in *THE JOURNAL* of November 29, p. 1411.

172. *Tubercular Joint Disease*.—The recommendation by some authorities of traction in tubercular joint disease is questioned by Tracy, who believes that effective fixation with a wood plastic splint is much better treatment. He reports cases. The method, he says, is as simple as it is effective.

1. Lunacy and the Law.—Gowers' address is a criticism of the English law, which, like that in some parts of this country, in its aim to protect the liberty of its citizens, has made it harder for the insane patients and tends to increase the numbers of hopeless cases by requiring commitment to asylums in every case where special treatment is needed, and it is also specially hard on the physicians in the heavy penalties it requires for every case of treatment of uncertified insane. The general result is that the law has to be broken at great risk or the patients suffer. He thinks also that the Lunacy Commission is overworked and should be increased, especially on its medical side. In both of these respects the Scotch law is very much superior to the English.

2. Acute Nervous Diseases.—Barr first calls attention to a class of cases which used to be called serous apoplexy, a name which has now gone out of date, but which he would like to see retained. These cases closely resemble cerebral hemorrhage, but the paralysis is rarely so absolute and the onset is more gradual like that of thrombosis, being as it is a serous congestion. These cases also occur in different classes, the apoplectic attacks occur in overfed persons, those with Bright's disease and high blood pressure with atheromatous vessels, while the other type occurs in the underfed and overworked individual with low blood pressure. The treatment of the two conditions is exactly opposite. In the cerebral hemorrhage you must reduce the blood pressure, while in the other you must raise the general blood pressure and increase the velocity of the circulation. The best drugs are caffeine and digitalis. The associations and causal conditions should receive attention. A sinapism and fly blister to the nape of the neck may do good. The later treatment consists of mental and bodily rest, good food and a long holiday. A case is reported. He also reports a case of paraplegia with cystitis which had in its symptoms resemblance to Landry's paralysis, but examination of the cerebrospinal fluid showed the presence of staphylococci. It would seem as if the patient's low vitality did not afford sufficient reaction to establish a meningitis, but the toxins had a paralytic effect on the motor centers of the cord. In a severe case of cerebrospinal meningitis in the same ward lumbar puncture showed staphylococci in the cerebrospinal fluid and no other organism. The patient whose case is reported was cured by the prone posture and an ice bag to the spine. His cold extremities were wrapped in cotton-wool, quinin, nitroglycerin and urotropin administered, and the bladder washed out with a chinolol solution for the cystitis. Rest and a liberal diet completed the cure.

11.—See also title 1, above.

12. Varicose Veins.—Varix is classed under three heads by Bennett in this address: 1. Congenital; 2, acquired; 3, intermediate. The first includes the vast majority of cases, though they may not have the affection noticeable from birth. By acquired varix he understands cases that come on through accident or otherwise, in veins that are primarily normal, but he doubts whether this ever occurs after adult life has been fully reached. He suggests that the tendency to varix is increasing in young girls on account of the habit of heavy physical exercise in the periods of rapid growth. By intermediate varix he means cases where the congenital defect is increased by injury or strain such as might give rise to acquired varix. The localized varices of the limbs are generally arranged in three main areas, along the line of the internal and external saphena veins and along the outer side and back of the thigh. These may exist singly or in combination with each other. The symptoms are largely pain, a feeling of tension and weight, and edema. The worst appearing cases often cause very little trouble. It rarely becomes obvious before puberty and in congenital cases the appearance of the varix is always prior to the

occurrence of the symptoms arising from it. In the acquired form, on the other hand, the feeling of discomfort and pain generally precede the physical manifestations and call attention to them. The periods of spontaneous increase usually occur at or soon after puberty, between the ages of 20 and 25, about the ages of 30 and 35 years, and between 45 and 50 years. If it shows no sign of increase at 50 years, it rarely occurs spontaneously afterwards. After 60 years there is a tendency for the normal vessels to diminish in size and trouble rarely arises in connection with these after that age unless from thrombosis, injury or some other similar cause. The treatment is either non-operative or surgical. The first he classes under hygienic, including careful avoidance of constipation, the use of careful feeding, close-fitting, well-ventilated underclothing on the limbs, and avoidance of extremes in temperature in the daily bath. He thinks the tepid bath is better than the very cold one. Manual treatment means massage and this may completely check the varix if applied early enough. The rubbing of the varicose parts with alcohol-night and morning is excellent. The method of application is applying it only over the varicose vessels and with only smooth rubbing. During the first part of the massage the limbs should be dependent or flat, and in the second they should be vertical. The association of electricity should be in the form of the electric bath with massage, which is very advantageous, but it is not easily available. The mechanical support he prefers is a well-applied porous bandage; its overuse and misuse is likely to do harm. The operative treatment requires a period of rest after the operation, of at least three weeks before the patient is allowed to make any attempt to walk and at least six weeks or two months before very active exercise is undertaken. He thinks the only way of mitigating the condition is the removal of a portion of the long saphena high up in the thigh, but never below the point in which the large posterior tributary of the inner and back part of the thigh joins the internal saphena. The improvement is more rapid if three inches of the saphena are removed immediately below the knee, but it is not absolutely necessary.

13. Pneumonia.—Washbourn's second lecture discusses the virulence of the pneumococci and the observations which he has made in conjunction with Eyre. He finds that the virulence varies within great limits. It is easily lost in artificial cultivation, and if the pneumococci will grow at 20 C. they are usually of only slight virulence. The virulence may be greatly increased by cultivation. It is found that animals immune against one strain of pneumococci are not necessarily immune against another. The pneumococci obtained from the mouths of healthy individuals are of less virulence and less easy to increase than those obtained from pathologic lesions. Immunization against streptococci does not protect, and it appears that the protective substance is manufactured in some organ in the body and thrown into the blood later. Wassermann has brought forward evidence that points to the bone marrow as the seat of the formation of protective substance of immunization. Washbourn and Eyre fail to find any definite relationship between the agglutinative power and the protective action of the different sera. The lecture reviews the results of other investigations in detail.

14. Tuberculosis.—Pearson has treated seven consecutive cases with urea according to the method advocated by Harper, and gives the details. He compares these with 100 cases treated otherwise. Of the 7 patients the average gain in weight was 4½ pounds, and the average length of stay in the hospital was three months. Of the 100 patients the average gain was 6¾ pounds in the same period of time. There was, moreover, a decided improvement in the general and physical condition, which was not the case with the 7. Attempts were made to measure the exact urea output, though there were some difficulties in securing this. He concludes that there is no stimulating action from the drug; it appears in no way to improve the pulse, the appetite or general vigor of the patient. He therefore summarizes its therapeutic action as follows:

1. Urea given by the mouth in patients with chronic pulmonary tuberculosis increases the output of the urea; but the total increase in this output does not, as a rule, equal the total quantity administered. 2. Urea acts only to a slight extent as a diuretic; this

action is variable and on the whole untrustworthy. 3. In both the output of urea and the output of urine the effect produced by the administration of urea is more marked at first. After a time the body seems to accustom itself to the intake of urea and tends to return to the normal output. 4. Urea does not act as a cardiac stimulant.

16. Transplantation by Exchange.—In the case here reported by Keetley a hairy mole on the left cheek was transferred to the arm in infancy. In placing the infant's arm against its face it was found that the whole skin of the outside of the upper arm from the shoulder down to the elbow would be required to replace the mole if the latter was cut away and filled in by flap transplantation. The operation chosen, therefore, was to exchange the hairy mole of the face and the smooth white skin of the arm, anchoring, so to speak, the arm to the head with strong sutures, which united the former to the transplanted mole, the two flaps lying with their two surfaces in mutual contact, and helping to keep up each other's warmth and nutrition. The risk of sloughing was diminished and there was no sacrifice of tissue. The case was reported at the time, and now, 15 years later, it is reported again with results. To-day the patient is fairly good-looking, but the hairy mole on the arm has grown considerably, while the face is clear. He adds these points in regard to the technic of such cases of which he has had considerable experience within the last sixteen years:

1. Not only the outline of the flaps but the chief points of suture should be carefully marked before the flaps are cut.
2. The knife used to divide the skin should be sharp.
3. Twelve days are not too long to leave the arm and face in contact.
4. It is neither necessary nor desirable to cover the site of operation with plaster of Paris; on the contrary the plaster bandages should be so applied as to leave it freely accessible and the dressings should be changed occasionally.
5. The stronger sutures should be of silkworm gut.
6. Care should be taken not to leave a fragment of mole behind. Cutting the flaps free is a difficult step in the operation, as they have to be cut where folded, and it is sometimes difficult to get a good view. A sharp knife should be used and a strong light should be thrown into the hollow. At the same time the skin should be carefully swabbed free of blood.
7. It should be made absolutely sure that both flaps are entirely cut through before the arm is allowed to move an inch away from the face.
8. The strappings used should be old-fashioned diachylon and not the irritating plasters often sold on rollers.
9. The iodoform gauze should be well rinsed out in warm sublimate solution 1 to 2000.
10. No drain of any kind should be inserted between the flap and its bed; it is not necessary and may be mischievous.

18. Mosquitoes.—Aitken continues his lecture describing the life, habits and peculiarities of the various mosquitoes in the North Canara district of India. He calls attention to the point that too early killing of the mosquitoes may not give a proper idea of their true specific characters. The mosquito does not attain its proper color for some time after emerging from the pupa.

19. Sleeping Sickness.—The point made by Crombie in regard to sleeping sickness is the suggestion to look into the deep cervical lymph glands of the neck for the *Filaria perstans*, as being the most likely real seat of the condition. Obstruction of the deep cervical glands, causing obstruction of lymph return from the brain, is especially, according to his idea, responsible for the symptoms in this disorder. He thinks the deep cervical lymphatics are rarely examined in postmortem researches, but reasoning by exclusion seems to narrow down the cause of symptoms to these organs.

20. Linear Serpiginous Pyodermitis.—Dubreuilh has observed 6 cases of this affection, in 2 women and 4 men, aged from 16 to 54. The pustulation follows an irregular wavy line. He never saw a line bifurcate, but several lines may radiate from the same point. The hand was affected in 2 cases, the arm once, the back and the axilla twice. The affection lasted from one to three months, not impairing the general health, but accompanied by much pruritus. It has no analogy with "creeping disease" or other affections of the kind that have been described, except its linear progression. Antiseptic treatment proved effective, especially a 1/30 solution of nitrate of silver once a day, supplemented by moist compresses or salves to facilitate removal of the scabs.

23. Cholera in Egypt in 1902.—Proust reviews the various epidemics of cholera in Egypt, and remarks that in 1895 the military surveillance of the canal had been suspended which allowed the entrance of cholera in that year. The present epidemic gained entrance by way of the Red Sea. It is to the interest of Europe and America, he proclaims, to prevent this

invasion of the Occident by way of the Red Sea. The sanitary supervision of this region should be in the hands of an international committee, uninfluenced by local affiliations. An international sanitary office should be established with headquarters in Europe, where all the sanitary data could be centralized and agents appointed to supervise the execution of the measures directed by the international sanitary conferences. This international board of health would have no executive power, but merely moral influence. No state would like to have its imperfections, its negligences held up to international reprobation. Each one would strive by every means to avoid this and the moral influence of such an international board would soon overcome the resistance or inertia of the countries still most refractory.

26. Digestion of Bacteria.—Turro found that juice, squeezed from the thyroid, kidney and the muscles of the pig and cow was able to dissolve in one to three days at a temperature of 35 to 38 C., a minimum of 10 per cent. of its weight of a one-day culture of the anthrax bacillus. The addition of 2 per cent. of sodium fluorid did not interfere with the process, but was useful in preventing the development of other bacteria. The white and yolk of egg possess similar digestive powers which increase with time. Older cultures are more resistant.

29. Present Status of Cytolytic Theory of Immunity.—London defines the three substances with which the organism is provided as 1, the desmons, the weapons for attack; 2, the alexins, the weapons for destruction, and 3, the antilyns (antitoxins), the weapons for defense. The degree of immunity depends on the quantity and quality of these three groups of substances, and artificial immunization is attained by promoting their production. Desmons can be produced by immunizing the animal with the cellular element in question. Alexins can not be produced in this way, and if they are not present in adequate amounts, the attempt to immunize fails. Antilyns can be artificially produced by injection of the corresponding lysins (toxins). The phagocytic theory and the humoral theory are merging now into what may be called the cytolytic conception of the struggle of the organism against disease.

30. Resistance of Plague Bacillus to Cold.—Toyama states that the plague bacilli in his tests did not lose any of their virulence or vitality by exposure to the winter weather at Tokio. The coldest day was four or five degrees below the freezing point. Others kept at ordinary incubator temperature proved to be less virulent by the fifty-sixth day and still less so after eighty-four days.

31. Tubercle Bacilli from Various Sources.—The results of De Schweinitz's research indicate the relationship between tubercle bacilli derived from diverse sources. They also emphasize the differences between attenuated and virulent human tubercle bacilli.

35. Cell Inclusions in Vaccine Foci in Cornea.—Gorini has long been advocating the biologic test of vaccine virus by inoculations on the cornea. This method of control has numerous advantages, simplicity, rapidity, etc., and also the fact that it determines not only the virulence of the virus, but also the absence of pathogenic germs. In his latest work in this line he has noticed "cell inclusions" similar to those observed in malignant neoplasms.

37. Medicated Steam Sterilization.—Kokubo proclaims that the addition of a disinfectant to the fluid materially enhances the sterilizing power of steam. Anthrax bacilli were killed in one minute in a 1 to 3 per cent. concentration of cedarwood oil, creosote, anisol, acetone, formaldehyd, etc.

40. Leuconostoc Hominis in Exanthematous Diseases.—Hlava has found the *Leuconostoc hominis* in the necrosed tonsils and in the blood in 21 scarlet fever patients; also in the tonsils, blood, sputum, nasal secretions and lungs in measles (8 cases), and in the tonsils and blood in spotted typhus. It was not pathogenic for animals. It resembles the streptococcus and has probably many times been classed as such, but it usually occurs in pairs or chains, which are enclosed in a kind of sheath. Some of the links also assumed a swollen or lance shape or formed coin rolls. It thrives best on Zopf's bouillon

and saccharose or beet sugar agar. On the latter in Petri dishes it grows projecting in the form of a raspberry above the surface.

46. Improved Technic for Formaldehyd Disinfection.—Voges writes from Buenos Ayres that he has solved the problem of disinfecting the goods of passengers on quarantined vessels in an hour and with very little traces of the odor left after disinfection. A vacuum is produced in the chamber in which the goods are placed to be disinfected, and the penetrating and disinfecting power of the formalin is immeasurably enhanced thereby. Every particle of moisture is greedily absorbed in a vacuum and the formalin penetrates rapidly everywhere. An hour's exposure is sufficient, and as much less formalin is required than by the usual methods, the odor is soon dissipated, and the bedding, etc., can be used at once. A new ship is to be constructed at Buenos Ayres for quarantine purposes, in which this principle of formalin disinfection in a vacuum will be applied on a large scale.

52. Simultaneous Immunization Against Several Infections.—Verney has been studying the mutual action of consecutive immunization against several infections in turn. He found that it was possible to confer agglutinating power against the typhoid, colon and pyocyaneus bacilli which coexisted simultaneously.

59. Further Applications of the Biologic Blood Test.—Schütze announces that it is possible to differentiate the sperma from different animals as well as human sperma by the specific prepared serums of the biologic blood test. It is not necessary to inject the animals with sperma; any organic fluid containing albumin, especially the blood serum, answers the purpose and produces the characteristic and specific reaction. Tests of various yeasts showed that the albuminoid substances in them must be identical, as even this sensitive test failed to disclose any differences between them.

60. Sudden Death from Enlarged Thymus.—Grawitz was the first to direct attention to the medicolegal importance of the enlarged thymus as a cause of sudden death. This communication from the pathologic institute of which he has charge describes two new cases. One was an infant who lived only two hours after version and birth, and the other was an apparently healthy six-month-old babe. Both died suddenly, and the only plausible cause of death was a very large thymus gland. In the second case the gland was in two lobes respectively 10 and 8.5 cm. long. The cases confirm the assumption that a large thymus may compress the trachea until it is actually flattened. If the head is thrown back or the throat assumes any unusual position, the trachea becomes completely occluded and suffocation ensues, although the compression heretofore may not have caused any appreciable symptoms. This explains certain sudden deaths in the water, as the head is thrown unusually far back in swimming. This may also cause unusual pressure on the veins of the neck, which in turn is liable to cause congestion of the gland and consequent increase of pressure. Siegel has reported the case of a child who had suffered from dyspnea for several weeks, finally relieved by tracheotomy and the introduction of a long tube extending to the bifurcation of the bronchi. The long canula caused ulceration and on the assumption that the enlarged thymus might be the cause of the dyspnea, the gland was drawn up after opening the mediastinum, and it was sutured to the fascia over the sternum. The child was completely freed from all his troubles.

61. A Cancer Not Arrested by Cancroin.—Adamkiewicz published a certain case as cured, but later reports show that the patient died within the year after the malignant disease in the esophagus had been positively diagnosed. The cancer continued its course unaffected by the injections of cancroin, although a total of 40 c.c. were injected in the course of four months, and at first the patient seemed to be relieved.

64. Conservative Treatment of Entropium.—When a patient refuses the knife, Oppenheimer has found it possible to cure the entropium by marking on the lower rim of the spectacles the point where pressure can best be applied to the lesion. The optician then fits a small shell along this edge. A pad, shaped something like a stirrup, is screwed into this shell

and bent to fit the lesion. By this arrangement the pad can be altered at will; the pressure is applied from the front, and it is impossible for the patient to hurt himself with this little contrivance, which is not at all conspicuous and is simple and inexpensive.

66. Immunization with Diphtheria Bacilli.—Lipstein has succeeded in producing a powerful immune serum by inoculating animals with large amounts of living or dead diphtheria bacilli after previously injecting diphtheria antitoxin. The result is an immune serum with great agglutinating power, but this power is most marked on the bacilli of the family from which the serum was derived. He suggests that a certain race of bacilli may possess certain receptors and that the resulting immune serum fits this receptor apparatus better than it fits any other.

67. Bandage for Upper Arm and Shoulder Fractures.—Heller's triangle bandage is readily understood from the cuts accompanying the description. It combines a number of advantages, not the least of which is its extreme lightness.

68. Recognition of Fetal Syphilis.—Hecker finds that in Hamburg and Munich from 30 to 35 of each thousand births in the five-year periods between 1881 and 1899 were prematurely or stillborn infants. He has dissected and examined under the microscope 62 of these cadavers and found that all but 26 per cent. were syphilitic, but that in more than half of the syphilitic fetuses there was no naked-eye evidence of syphilitic manifestations. All but 17 of the cadavers were macerated when examined, and the liver was so altered that no nuclei would take the stain in 96 per cent.; the pancreas in 84 per cent.; the spleen in 56; the thymus in 32, but the kidneys and bones in only 10 per cent. In 24 per cent. of all, the kidney was the only organ not too much macerated for examination. The frequency with which the various organs participated in the syphilitic manifestations was: kidney, in 90 per cent. of 29 cadavers examined; the spleen in 61 per cent.; the thymus in 50 per cent.; the pancreas in 46 per cent.; the liver in 23 per cent. of 31 examined and the lungs in 17 per cent. The liver, therefore, is not so important for the diagnosis of hereditary lues as generally accepted, while it is the first organ to show the effects of maceration. If there are no naked-eye evidences of syphilis in a suspicious case he advises hardening or making frozen sections of scraps of the kidney, spleen, thymus, pancreas, lung and liver. Examine the kidney first, and the finding of cellular infiltration of the smaller vessels will render further investigation superfluous. The lack of all pathologic phenomena in the scraps named above, investigated in turn, from an unmacerated fetus, excludes syphilis. In a number of cases the macroscopically diagnosed osteochondritis proved to be merely an imperfect technic. Cellular infiltration of the walls and environment of the smallest cortical arteries in the kidneys is pathognomonic for syphilis. It is probably an incipient inflammatory process, the first stage of interstitial inflammation. The blood current becomes slower in these finest arteries and the syphilitic virus has the opportunity to make its influence felt here first of all. Other changes in the kidneys are occasionally noted in the connective tissue and epithelium and the development of the organ may be arrested or exaggerated. Karvonen's "mathematical method" of counting the glomeruli is of little practical value as yet.

69. Cholelithiasis and Affections of Pancreas.—Fuchs corroborates Opie's statement in regard to the importance of cholelithiasis as a factor in acute hemorrhagic pancreatitis. He goes still further and incriminates it in the etiology of all affections of the pancreas, especially inflammation with tumefaction, and claims that a clinical diagnosis is possible in all such cases. It is reasonable to suppose that the pancreas is pathologically affected as often as the stomach, liver, gall bladder or intestines, and yet we seldom think of it in formulating a diagnosis, but refer the symptoms to the other organs. Many a so-called catarrhal icterus or nervous gastralgia may in future prove to be some affection of the pancreas. As pancreatitis, with the exception of the acute hemorrhagic form, may be cured by operative measures, the pancreas should be examined from this point of view and the possibility of some

The Public Service.

Army Changes.

Movements of Officers of the Medical Department of the U. S. A., under orders from the Adjutant-General's Office, Washington, D. S., from Nov. 21 to Nov. 27, 1902, inclusive:

Arthur, William H., major and surgeon, U. S. A., having reported in person in this city to the Surgeon-General of the Army, in compliance with orders heretofore issued, will proceed to New York City, and assume the duties of attending surgeon and examining of recruits in that city, to relieve First Lieut. Theodore C. Lyster, asst.-surgeon, U. S. A.

Allen, Ira A., captain and asst.-surgeon, U. S. V., now serving in the Division of the Philippines, is honorably discharged from the service of the United States, to take effect Nov. 25, 1902, his services being no longer required.

Black, Allen J., captain and asst.-surgeon, U. S. V., as Capt. Allen, above.

Bowen, Edward N., captain and asst.-surgeon, U. S. V., as Capt. Allen, above, to take effect Nov. 24, 1902.

Boyd, Robert, captain and asst.-surgeon, U. S. V., is honorably discharged from the service of the United States, to take effect Dec. 18, 1902, his services being no longer required.

Borden, William C., major and surgeon, U. S. A., is detailed to represent the Medical Department of the Army at the third annual meeting of the American Roentgen Ray Society, to be held at Chicago, Dec. 10 to 11, 1902. Major Borden will proceed to Chicago in time to reach that place on or before Dec. 10, 1902, and on the adjournment of the society, will return to his proper station.

Birmingham, Henry P., major and surgeon, U. S. A., is relieved from duty at Fort Leavenworth, Kan., to take effect on the arrival at that post of Lieut.-Col. John Van R. Hoff, deputy surgeon-general, U. S. A., and will then proceed to Washington Barracks, D. C., and report in person to the commanding officer of that post for duty, and by letter to the commanding general, Department of the East, to relieve Capt. John H. Stone, asst.-surgeon, U. S. A.

Chaffee, Jerome S., first lieut. and asst.-surgeon, U. S. A., is relieved from duty at the Army and Navy General Hospital, Hot Springs, Ark., to take effect on the arrival at the hospital of Contract Surgeon James C. Minor, U. S. A., and will then proceed to Plattsburgh Barracks, N. Y., and report in person to the commanding officer of that post for duty and by letter to the commanding general, Department of the East.

Clausius Max F., contract surgeon, U. S. A., is relieved from duty at Fort Huachuca, Ariz., and will proceed to his home, Barrington, Ill., and on arrival report by letter to the Surgeon-General of the Army for annulment of contract.

Lyster, Theodore C., first lieut. and asst.-surgeon, U. S. A., on being relieved from duty in New York City will proceed to Fort Schuyler, N. Y., and report in person to the commanding officer of that post for duty and by letter to the commanding general, Department of the East.

Minor, James C., contract surgeon, U. S. A., now at Hot Springs, Ark., will report in person to the commanding officer of the Army and Navy General Hospital at that place, for duty.

Phillips, John L., major and surgeon, U. S. A., having reported his arrival at Governor's Island, New York, in compliance with orders heretofore issued, will report in person to the commanding officer, Fort Columbus, N. Y., for duty at that post and by letter to the commanding general, Department of the East, to relieve Major William H. Corbusier, surgeon, U. S. A.

Major Corbusier, on being thus relieved will proceed to Fort D. A. Russell, Wyoming, and report in person to the commanding officer of that post for duty and by letter to the commanding general, Department of Colorado, to relieve Capt. William F. Lewis, asst.-surgeon, U. S. A.

Capt. Lewis, on being thus relieved, will proceed to San Francisco, and report in person to the commanding general, Department of California, for transportation to the Philippine Islands, where, on arrival, he will report in person to the commanding general, Division of the Philippines for assignment to duty.

Repetti, John J., captain and asst.-surgeon, U. S. V., is honorably discharged from the service of the United States, to take effect Dec. 31, 1902, his services being no longer required. He will proceed to his home.

Rutherford, Henry H., first lieut. and asst.-surgeon, U. S. A., having completed the duty for which he was ordered to this city by Special Orders, No. 259, Nov. 17, 1902, Department of California, will return to his proper station.

Rutherford, Henry H., first lieutenant and asst.-surgeon, has been granted an extension of leave for one month.

Strong, Richard P., first lieut. and asst.-surgeon, U. S. A., is relieved from duty in the Division of the Philippines, and will report to this city and report in person to the Surgeon-General of the Army for duty in his office.

Stark, Alexander N., captain, and asst.-surgeon, U. S. A., is detailed to represent the Medical Department of the Army at the annual meeting of the American Public Health Association, to be held in the city of New Orleans, La., Dec. 8 to 12, 1902, and will proceed via Washington, D. C., to New Orleans in time to reach the latter place on or before December 8, 1902, reporting en route to the Surgeon-General of the Army for conference. On the adjournment of the association Capt. Stark will return to his proper station at West Point, New York.

Stone, John H., captain and asst.-surgeon, U. S. A., on being relieved from duty in the Department of the East, will proceed to Fort Leavenworth, Kan., and report in person to the commanding officer of that post for duty and by letter to the commanding general, Department of the Missouri.

Truby, Albert E., first lieut. and asst.-surgeon, U. S. A., is relieved from further duty at the U. S. General Hospital, Washington Barracks, D. C., and will proceed to West Point, N. Y., and report in person to the superintendent of the U. S. Military Academy for duty, to relieve First Lieut. James R. Church, asst.-surgeon, U. S. A., from temporary duty at that place.

Lieut. Church, on being thus relieved, will return to his proper station at the U. S. General Hospital, Washington Barracks, D. C. The following named officers, now serving in the Division of the Philippines, are honorably discharged by the Secretary of War from

the service of the United States, to take effect Nov. 24, 1902, their services being no longer required:

Maj. John R. Hereford, surgeon, U. S. V.; Maj. Samuel C. de Krafft, surgeon, U. S. V.; Capt. Bruce Ffoulkes, asst.-surgeon, U. S. V.; Capt. Waller H. Dade, asst.-surgeon, U. S. V.; Capt. William H. Tukey, asst.-surgeon, U. S. V.; Capt. George H. Jones, asst.-surgeon, U. S. V.; Capt. Ira Ayer, asst.-surgeon, U. S. V.; Capt. Wilson Murray, asst.-surgeon, U. S. V.; Capt. Julius A. Escobar, asst.-surgeon, U. S. V.; Capt. Milton Vaughn, asst.-surgeon, U. S. V.; Capt. William O. Cutliffe, asst.-surgeon, U. S. V.; Capt. Frank L. R. Tetamore, asst.-surgeon, U. S. V.

Van Poole, Gideon McD., first lieut. and asst.-surgeon, U. S. A., is relieved from further temporary duty at the Army and Navy General Hospital, Hot Springs, Ark., and will proceed to Fort Riley, Kan., and report in person to the commanding officer of that post for duty and by letter to the commanding general, Department of the Missouri.

The following named officers now serving in the Division of the Philippines are honorably discharged by the Secretary of War from the service of the United States, to take effect Nov. 25, 1902, their services being no longer required: Capt. Josiah M. Ward, asst.-surgeon, U. S. V.; Maj. William H. Cook, surgeon, U. S. V.; Capt. Oscar W. Woods, asst.-surgeon, U. S. V.; Capt. Charles H. Stearns, asst.-surgeon, U. S. V.; Capt. Harold L. Coffin, asst.-surgeon, U. S. V.; Capt. Harry H. Eberle, asst.-surgeon, U. S. V.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ended November 29:

A. A. Surgeon B. F. Jenness, appointed asst.-surgeon, Nov. 11, 1902.

Pharmacist J. F. Pearson, detached from the Naval Academy and ordered to the Naval Training Station, Newport, R. I.

Surgeon G. P. Lumsden, detached from the *New York* and ordered to the *Hancock*.

P. A. Surgeon E. M. Ship, detached from the Naval Station, Cavite, P. I., and ordered to the *Wilmington*.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Nov. 29, 1902:

SMALLPOX—UNITED STATES.

California: Sacramento, Nov. 8-15, 2 cases; San Francisco, Nov. 9-16, 3 cases.

Colorado: Denver, Nov. 8-15, 3 cases.

Illinois: Chicago, Nov. 15-22, 6 cases.

Indiana: Nov. 15-22, Indianapolis, 3 cases; Kokomo, 1 case.

Kentucky: Lexington, Nov. 15-22, 1 case.

Maine: Biddeford, Nov. 15-22, 9 cases.

Massachusetts: Nov. 15-22, Boston, 36 cases, 4 deaths; Clinton,

1 case; Weymouth, 1 case.

Michigan: Grand Rapids, Nov. 15-22, 6 cases.

New Hampshire: Nashua, Nov. 15-22, 12 cases.

New Jersey: Camden, Nov. 15-22, 2 cases; Jersey City, Nov. 8-16,

1 case.

New York: New York, Nov. 15-22, 1 case.

Ohio: Cincinnati, Nov. 14-21, 6 cases; Cleveland, Nov. 15-22, 12

cases, 4 deaths; Dayton, Nov. 15-22, 1 case; Hamilton, Nov. 15-22,

4 cases; Toledo, Nov. 8-22, 15 cases.

Pennsylvania: Nov. 15-22, Altoona, 2 cases, 1 death; Erie, 23

cases; Johnstown, 5 cases, 1 death; McKeesport, 4 cases, 1 death;

Pittsburg, 46 cases, 7 deaths.

Rhode Island: Providence, Nov. 15-22, 1 case.

South Carolina: Charleston, Nov. 15-22, 2 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Nov. 1-8, 17 cases.

Belgium: Ghent, Oct. 18-Nov. 8, 10 deaths.

Brazil: Bahia, Oct. 19-Nov. 1, 6 cases.

Ecuador: Guayaquil, Nov. 1-8, 2 deaths.

Great Britain: Dundee, Nov. 1-8, 2 cases; London, Oct. 25-Nov.

8, 6 cases.

India: Bombay, Oct. 21-28, 3 deaths; Calcutta, Oct. 18-25, 1

death.

Italy: Naples, Nov. 3-10, 4 cases; Palermo, Nov. 1-8, 2 cases.

Mexico: Mexico, Nov. 2-16, 1 case, 2 deaths.

Russia: Odessa, Oct. 18-26, 1 case; St. Petersburg, Oct. 24-Nov.

1, 16 cases, 3 deaths.

Straits Settlements: Singapore, Sept. 27-Oct. 11, 3 deaths.

YELLOW FEVER.

Colombia: Panama, Oct. 10-17, 5 cases.

Costa Rica: Port Limon, Nov. 1-8, 1 case, 1 death.

Ecuador: Guayaquil, Oct. 26-Nov. 8, 3 deaths.

Mexico: Mexico, Nov. 2-16, 2 cases, 1 death; Vera Cruz, Nov. 8-

15, 16 cases, 2 deaths.

CHOLERA—INSULAR.

Philippine Islands: Manila, Sept. 28-Oct. 5, 32 cases, 24 deaths;

Manila, Oct. 6-12, 23 cases, 13 deaths; Provinces, Sept. 28-Oct. 5,

9,263 cases, 5,276 deaths; Provinces, Oct. 6-12, 5,658 cases, 3,274

deaths.

CHOLERA—FOREIGN.

Egypt: Alexandria, Oct. 26-Nov. 1, 29 cases, 32 deaths.

India: Calcutta, Oct. 18-25, 16 deaths.

PLAGUE—UNITED STATES.

California: San Francisco, Nov. 15, 1 case, 1 death; Nov. 18, 1

case, 1 death.

PLAGUE—FOREIGN.

Australia: Queensland, Brisbane, July 1-31, 1 death.

India: Bombay, Oct. 21-28, 142 deaths; Calcutta, Oct. 18-25, 9

deaths; Karachi, Oct. 19-26, 14 cases, 10 deaths; Madras, Oct. 11-

17, 1 death.

Russia: Odessa, June 1-Oct. 26, 49 cases, 17 deaths.

TYPHOID FEVER AND WATER SUPPLY IN CHICAGO.

EDWIN OAKES JORDAN.

ASSOCIATE PROFESSOR OF BACTERIOLOGY, UNIVERSITY OF CHICAGO.
CHICAGO.

The severity of the recent epidemic of typhoid fever in Chicago has given rise to some discussion concerning the relation of the city drinking water to the outbreak, and considerable interest has been aroused in the future possibilities, as well as the present conditions, of drainage disposal and water supply.

The matter is of far more than local concern. The character of the Chicago water supply affects not merely the large body of persons continuously dependent on this supply, but also all those living in the territory immediately surrounding the city and commercially connected with it. In fact, all the communities of the middle west whose citizens visit Chicago at frequent or at occasional intervals are vitally interested in the quality of the Chicago water supply. Not only is the health of individual visitors endangered by a polluted water, but cases of typhoid fever contracted in Chicago may be imported into other towns and serve as new foci for the spread of the disease, thus enlarging the circle of vicious influence to wide limits. A few years ago it was shown on investigation of the origin of an excessive number of deaths from typhoid fever in a small city over a hundred miles from Chicago that more than half of the cases were clearly contracted in Chicago, and that half of the others could be traced to infection in another city that used unfiltered surface water.¹

The position of Chicago as a railroad center, moreover, entails special and often unregarded responsibility. The tanks of drinking water on the passenger cars which are daily sent out from the city to all points of the compass are often filled directly from the city supply, and if the supply is contaminated one can easily see how infection may thus be spread broadcast among scores of innocent communities.

The special problems of water supply and sewage disposal that confront Chicago are similar to those that must be faced by many other large interior cities in this country, especially those deriving their water supply from the Great Lakes. For this reason, as well as for others that need not be mentioned, the epidemiology of typhoid fever in Chicago can not be looked on as a question of merely local importance.

It is a fact that typhoid fever has for years prevailed excessively in Chicago (Table 1), and that Chicago has apparently suffered from this disease more severely than

any other large American city (cf. e. g., New York, Philadelphia and Boston, Tables 2, 3 and 4).

TABLE 1.—TYPHOID FEVER IN CHICAGO,* 1851-1900.

Years.	Population.	Deaths from All Causes.	Typhoid Fever.		
			Number of Deaths.	Per Cent. of All Deaths.	Per 10,000 Inhab.
1851.....	34,000	927	10	1.08	2.94

1899.....	1,626,410	25,503	442	1.73	2.72
1900.....	1,698,575	24,941	337	1.35	1.98

* Based on statistics published in the annual reports and bulletins of the Department of Health of the City of Chicago.

† Large territory annexed in 1899. No population annexed between 1890 and 1900.

‡ The figures for these two years are according to the U. S. census. The population of the intervening years has been estimated by the writer on the Registrar-General's method (Newsholme, Vital Statistics, 1899, pp. 5-6). To the figures thus obtained for 1892 and 1893, 35,000 and 70,000 have been added respectively. Any estimate of the floating population in the city during the year of the World's Fair and the preceding year must, however, be regarded as only approximate.

* Based on statistics published in the annual reports of the Health Department of the City of Boston.

The marked and constant excess of typhoid fever in Chicago which is shown in Table 1 has been generally attributed to the pollution of the city water supply.²

Since a very early period in the history of the city the extraordinary practice has prevailed of allowing a portion of the sewage to flow into Lake Michigan, which has been at once the recipient of the city refuse and the source of the city water supply. A large number of the city sewers have for some time emptied into the small stream known as Chicago River, which on this account has achieved a widespread and unenviable notoriety. As long ago as 1865 the uneasiness that was naturally felt regarding the effect of such conditions on the public health led to the use of a pumping station at Bridgeport, situated at the junction of the Illinois and Michigan Canal with the south branch of the Chicago River. This station was originally established simply for supplying water to the canal, but in the year mentioned the Board of Public Works made arrangements for utilizing the pumping works to cleanse the river, and up to the year 1900 the river water, which in late years has been practically crude sewage, was more or less regularly pumped into the canal. The capacity of the pumping works was enlarged from time to time to keep pace with the growth of the city and the attendant increase of pollution, and as an additional precaution the water tunnels were pushed further and further out into the lake in the hope of escaping the sewage outflow. Both these means failed, however, to give more than a temporary relief. The working of the pumps at Bridgeport had the effect under ordinary conditions of reversing the flow of the Chicago River and of causing a sluggish current to set away from the lake. Occasionally, however, the pumps were unable to cope with variations in the lake levels, and the floods caused by sudden and heavy rains flushed far out into the lake the unspeakable filth of the Chicago River. The results of this critical situation might have been, and indeed were foreseen. On more than one occasion Chicago has suffered severely from typhoid fever, a disease known to be caused by polluted water. One of the most serious epidemics occurred in 1891, when there were 1,997 deaths from typhoid fever in twelve months, a number larger than that occurring during the same period in the state of New York with a population five times as great. The death rate from typhoid fever in Chicago in 1891 was seven times as great as that in the city of New York and eleven times that in the city of London. From the year 1892 up to the present year no epidemic of such alarming proportions has visited the city, but the death rate from typhoid fever and kindred diseases has remained persistently high, and on several occasions, especially in the seasons of heavy rains or melting snow, miniature epidemics have unduly swollen the death rate for a few months. The recent epidemic has proved the most extensive that has occurred since 1892, and is one of the worst that the city has ever experienced.

TABLE 5.—DEATHS FROM TYPHOID FEVER IN CHICAGO BY MONTHS.

It will be noticed (Table 5) that in August and September of the present year 358 deaths were recorded,

a number somewhat larger than the total reported for the whole twelve months of 1900 (337). The deaths in August, 1902 (193), exceeded the number reported for any month since July, 1892 (211).

The epidemic of 1902 has caused much surprise and some consternation among the citizens of Chicago for the reason that the opening of the Drainage Canal was very generally regarded as marking the close of the excessive water pollution that had previously existed. As is well known, the canal is designed to conduct into the Illinois River the sewage of Chicago, diluted to such a degree with the pure water of Lake Michigan as to occasion no danger or inconvenience to the inhabitants of the Illinois valley. To this end the Chicago River, into which most of the sewers still empty, is made the main feeder of the canal, and a steady current away from the lake is produced in the river by gravity flow. The velocity of the flow is regulated by controlling works at Lockport, some thirty-three miles from the mouth of the river. The canal was opened early in 1900, and the belief that typhoid fever would never again prevail so extensively as in the past received almost immediate support in the low death rate from typhoid fever that was recorded in that year. In 1900 the typhoid fever death rate was the lowest that had ever been reported (1.98) in the sanitary history of the city (Table 1), and the total number of deaths from typhoid fever was smaller (337) than in any year since 1880, when the population of the city was less than one-third as great as in 1900. This low death rate, which followed the opening of the canal and was accompanied by a visible improvement in the Chicago River, naturally encouraged the feeling that great epidemics of typhoid fever in Chicago were not likely to recur, and that a marked and permanent improvement in the water supply had been effected.

As a matter of fact these sanguine expectations were not wholly justified by the conditions of drainage and water supply that obtained in 1900, and, indeed, still persist up to the present time. Through a lack of foresight and co-ordinated endeavor on the part of the responsible authorities, a large part of the sewage system of Chicago remains at this date unconnected with the Drainage Canal. An "intercepting sewer" is in process of construction along the lake shore in the southern section of the city, and another (the Lawrence Avenue sewer) north of the Lincoln Park district. It is said that the latter will be finished within a short time, but that the sewer running from the neighborhood of 39th Street to 87th Street will require several years for completion. Meanwhile a population of more than two hundred thousand, closely fringing the lake front, will continue to drain into the lake and pollute the water supply with crude sewage.

The accompanying diagram (Fig. 1)* illustrates with sufficient vividness the present relations of drainage and water supply. The shaded portion represents the territory now draining into the sanitary canal. It is evident that under the existing circumstances the occurrence of a sudden and heavy rainfall may be sufficient to lead to the mingling of a large amount of fresh sewage with the lake water. Until such time as the intercepting sewers and the connecting 39th Street sewer are completed and the pumps at 39th Street are in working order little relief from this situation can be anticipated.

Doubt has been expressed in some quarters as to whether the recent outbreak of typhoid fever was in

reality due to the water supply, and the opinion has been advanced that other factors should be sought for. The especially severe incidence of the disease on some of the congested districts of the city has been thought by some to point to a more localized cause for the epidemic. Apart from the facts already set forth regarding the abundant opportunities that exist for the entrance of fresh sewage into the drinking water, there are certain other considerations which indicate unmistakably that the outbreak was primarily, at least, of water-borne origin. In the first place the dimensions of the epidemic and the fact that all sections of the city have suffered seriously, if not perhaps equally, must, on epidemiologic

Fig. 1.—Map of the City of Chicago, showing the districts draining into the Sanitary Canal. Oct. 1, 1902.

grounds, be looked on as convincing evidence of water infection. Epidemics of typhoid fever due to infected milk, to oysters or to other raw foods are more limited in character, and rarely if ever involve large masses of population. There seems to be no instance on record where a large city possessing a pure or purified water supply has experienced an epidemic of typhoid fever of the proportions of the one that has just visited Chicago. The low and relatively uniform death rate from typhoid fever in Berlin, London and Vienna, all cities which possess good water supplies, may be contrasted with the violent fluctuations in the death rate from this disease in Chicago and Philadelphia (Fig. 2).

* I am indebted to Prof. J. H. Long for the material from which this figure was constructed.

The majority of typhoid fever epidemics both large and small are due to water infection. Schüder³ has recently collected information concerning the etiology of 650 separate outbreaks of typhoid. Over 70 per cent. (462) of these were outbreaks caused by water, and if the number of the persons affected in the various outbreaks had been enumerated the proportion of individual cases due to water infection would doubtless have been found even higher.

It is probably true that typhoid fever is sometimes spread by means of infected dust. The experiments of Firth and Horrocks⁴ indicate that from ordinary soil, allowed after inoculation with the specific bacillus to become so dry as to be readily blown about as dust, the bacillus can be recovered as late as the twenty-fifth day after inoculation, and the authors conclude that typhoid *infective material can be readily translated from dried soil and sand by means of wind and air currents.* In

ever been clearly traced. The experiments of Neisser⁵ indicate that a velocity of 1.7 cm. per second is necessary to raise the typhoid bacillus in dust to a height of 80 cm., and according to Flügge⁶ the currents of air in closed apartments do not attain a velocity greater than $\frac{1}{4}$ mm. Dust infection in houses, then, must be extremely rare, and this explanation is hardly to be resorted to in the case of an extensive city epidemic. It is probable that some of the outbreaks that have been at times attributed to dust carriage may be more reasonably traced to the agency of flies,⁷ which, as is well-known, are capable, after visiting infectious material, of readily infecting various foods on which they may alight. It is stated on good authority that unclosed privy vaults and cesspools are still allowed to exist in some of the most densely populated districts of Chicago, and if this is the case it is certainly possible that in the recent epidemic flies may have had much to do with the incidence of the disease on the poorer quarters of the city.

Among other causes which have been suggested to account for the epidemic is an unusual infection of vegetables, of milk, and of other foodstuffs. It can not be doubted that some of the cases of typhoid fever occurring from time to time in every large city are due to this cause, but here again it is difficult to understand how even extraordinary accidents affecting milk and food could lead to the sudden and almost simultaneous infection of several thousand persons in different sections of the city. As a matter of fact, there is every reason to anticipate that minor epidemics of typhoid fever due to infected milk, to infected raw vegetables, to the agency of flies and other insects, and to what has been called secondary infection will follow in the wake of a great outbreak. A striking instance of the way in which typhoid fever may be perpetuated and disseminated in a community with naive or unsanitary habits of life has been described by Sedgwick.⁸ In the words of this writer: "It is easy . . . to understand how dirt, diarrhea and dinner too often get sadly confused." Whenever a large number of cases of typhoid fever exist in a community the superabundance of infectious material naturally increases the opportunities for diffusion. The chances that milk supply or food supply may become a source of infection are plainly greater at the time of an epidemic than when the disease is comparatively rare. It is unquestionably correct to recognize the danger of spread by secondary infection, by the agency of flies and by infected raw foodstuffs, but these factors, important though they are, play a subordinate rôle as compared to water infection.

If Hamilton's law of parsimony can be properly applied to epidemiologic matters, there is no question as to what is the most reasonable explanation of the recent outbreak of typhoid fever in Chicago. While some of the factors just enumerated perhaps contributed to the high death rate during August and September, there is no reason for considering any or all of them as the primary cause. The known and universally admitted facts regarding the water supply are of such a character that the excessive pollution of this supply through the unusually heavy rains of June and July furnishes a sufficient reason for the outbreak.⁹ Since there is at hand an explanation so simple, so in accord with the general experience regarding extensive epidemics of typhoid,¹⁰ and so consonant with the past experience of Chicago itself, it would seem logically unnecessary to seek for another cause.

Figure 2.

connection with the present outbreak in Chicago, the definite hypothesis has been advanced that the flooding of cellars and basements from *overcharged sewers*—an incident said to have happened in many parts of the city—has led to the introduction of typhoid bacilli into dwelling houses. It is conceived that with the receding of the waters the stranded typhoid germs might pass into the air and be inhaled by the inhabitants of houses thus affected. This view does not seem to be supported by any epidemiologic evidence, since it has not been shown that any more cases of typhoid fever have occurred in houses with flooded basements than in more favorably situated dwellings. While dust infection is indeed a possibility, few outbreaks from this source have

As has already been stated, the completion of the intercepting sewers, which will conduct into the Drainage Canal the sewage of a population aggregating 180,000 in the vicinity of the Hyde Park water intake, and that of a population of 25,000 in the neighborhood of the Lake View water intake, will lead to material improvement in the character of the supply (see Fig. 1). It may be taken as axiomatic that when a large amount of sewage is kept out of a public water supply typhoid fever will be less prevalent in the community served by that supply. It can not be forgotten that the lowest death rate ever recorded from typhoid fever in Chicago was in 1900, immediately after the opening of the Drainage Canal (Table 1), and that during the first six months in each of the three years 1900, 1901 and 1902 the deaths from typhoid fever were less numerous than for any similar period during the preceding decade (Table 5). No one will question, therefore, that the opening of the Drainage Canal has already effected a definite improvement in the quality of the water supply, and through that in the typhoid fever death rate. It may be confidently expected that when the population of 200,000 which now drains into the lake (Fig. 1), and which is so close to the lake front that its drainage must reach the lake in a fresh condition and therefore be peculiarly dangerous, becomes properly connected with the canal the deaths from typhoid fever will diminish still further. It is certainly singular that the present situation should not have been foreseen and guarded against. The excuse for allowing a large portion of the population, constituting from its topographical position the greatest menace to the city water supply, to pour fresh sewage into the lake for upward of three years after the completion of a great and enormously expensive sanitary undertaking can hardly be adequate.

While it is generally known that the acutely dangerous situation represented by the map (Fig. 1) is only temporary, it is not so widely understood that even the completion of the intercepting sewers will not mark the final solution of the water problem for Chicago. No one familiar with the general sanitary history of water supplies can expect that all chances for water pollution will cease with the completion of the sewerage system. The lake water near the intakes will still be exposed to possibilities of infection from passing vessels, from excursion steamers, from bathers and other sources. It might perhaps be supposed that these sources of contamination could be safely neglected, but when it is remembered that typhoid bacilli may persist in the urine far into convalescence and that as many as 172,000,000 individual germs have been found in one cubic centimeter of the urine,¹¹ it is evident that a single discharge of urine from a typhoid fever convalescent might render many gallons of water capable of conveying disease. The famous Plymouth epidemic,¹² in which 1,104 persons contracted typhoid fever and 114 died, was caused by the discharges from a single case of the disease, and the infectious material, moreover, had to pass through three storage reservoirs with a combined capacity of 5,000,000 gallons. Practically all unfiltered surface waters are at the mercy of accidents of this character, and the possibility of occasional infection can not be ignored.

In fact, the experience of the city of Zurich¹³ shows that the incidental pollution of a body of water of considerable size is not to be considered with indifference. The water supply of Zurich is drawn from the lake of the same name, and although no public sewers empty

into the lake, there is opportunity for pollution in the ways noted above, and it is said that the incidental contamination of this sort has apparently increased with the growth of the city. This pollution from sources other than sewers reached such an extent that sand filtration was resorted to in 1886 as a means of checking the increase in typhoid fever. For the six years before the introduction of filtration the annual typhoid fever death rate was 6.9 per 10,000 inhabitants, and for the six years after it was only 1.0; the improvement is attributed by the local authorities to the purification of the water supply. A similar increase in the pollution from non-sewerage sources has been observed in Mystic Lake at Boston, although in this case the body of water affected is much smaller than at Zurich. In Germany the use of unfiltered surface water for municipal supplies is altogether prohibited.

The probable increase in the incidental pollution of Lake Michigan, important as this may ultimately prove to be for the problem of a pure water supply for Chicago, does not, however, press for consideration so much as another question. This concerns the limitation in the boundaries of the area for which drainage is or is about to be provided. The present sanitary district of Chicago does not include either the independent towns and villages along the north shore or the rapidly growing part of the city itself lying south of 87th Street (see map). The Calumet sewer district has a resident population of 71,269, and is said to be growing rapidly. W. L. Marshall, United States Government Engineer, in his report¹⁴ of 1892, estimates the pollution of the Calumet River to be equivalent to that caused by a population of 700,000, owing to the number of persons and manufacturing establishments along the course of the river. While manufacturing refuse is not perhaps so objectionable on sanitary grounds as house sewage, this high degree of pollution is worthy of concern. As will be seen by reference to the map, the drainage from the Calumet region constitutes a particular menace to the water intake supplying the southern section of the city. No provision has yet been made for dealing satisfactorily with the sewage of this territory, although it is manifest that, at least so far as the Hyde Park water supply is concerned, the untrammelled discharge of the Calumet sewage into Lake Michigan threatens the health of the city (Fig. 1). A project for draining this area into the sanitary canal has been urged at various times, but as a large extent of rather thinly populated territory is involved, the expense to the resident taxpayers has proved a serious barrier, and in fact a measure proposed for this end was overwhelmingly defeated at the polls. Whatever course is finally adopted in regard to the Calumet sewerage it will probably have to be undertaken at the expense of the city of Chicago. In the absence of any policy the citizens of Chicago risk a repetition of conditions like those that have led to the recent distasteful outbreak of typhoid fever.

The question of the most suitable means of protecting the water supply against this source of pollution is therefore an urgent one at this time. The plan that has been most seriously considered is the construction of a canal from the lake at Calumet to join the sanitary canal at the "Sag." This would involve, it is stated, very nearly twenty-four miles of constructive work and is estimated by the chief engineer of the Drainage Board to cost \$11,879,854. The history of engineering undertakings of this class would seem to indicate that this limit might possibly be exceeded.

There is at least one other possible method of dealing

with the Calumet situation which does not appear to have been as yet fully discussed. This is the possibility of purifying the Hyde Park water supply by the method of slow sand filtration which is so successfully employed in Berlin, London, Hamburg and many other European cities. The total amount of water pumped by the 68th Street station in 1900 was 22,573,449,573 gallons, and the daily average 61,845,067 gallons.¹⁵ The cost of constructing a filtration plant for this amount of water under the conditions prevailing locally is, of course, a matter for detailed expert investigation, but the experience of other American cities may possess some interest, even if not directly applicable. The city of Albany, N. Y., installed in 1899 a filtration plant that is capable of yielding 14,700,000 gallons daily, at a cost of \$196,633. Assuming that substantially the same ratio would hold for the treatment of the Hyde Park water, and there are some reasons for believing that the advantage would be on the side of the latter, the cost of construction of suitable filtration works would fall between \$2,000,000 and \$2,100,000. Land for the purpose could perhaps be obtained near the present pumping station at the southern end of Jackson Park, and since, as has been found in several European cities, the presence of filter basins is by no means incompatible with the aims of landscape gardening, it is possible that a tract of land might be granted by the South Park Commissioners. Even if land had to be purchased outright or made by filling in along the lake front, the cost in this neighborhood should not be exorbitant. There seems every reason to suppose that the dune-sand found so abundantly along the shore of Lake Michigan would prove suitable for the construction of the sand beds, and that the expense of transporting the material would therefore not be excessive.

The expense of operating a sand filter increases with the amount and turbidity of the water treated. The cost of operation for twenty years at Poughkeepsie, N. Y., with the moderately turbid Hudson River water has averaged \$3 per million gallons of filtered water.¹⁶ In England and Germany the cost of operation is much lower than this, but the economic conditions obtaining in the United States render it probable that the Poughkeepsie figures would represent a fair average, although, of course, local conditions differ widely. Supposing that in Chicago the cost of operation ranged even as high as \$4 per million gallons, the annual cost of operation would amount to \$90,292, or a capitalization of about \$2,250,000 on a 4 per cent. basis. Although the estimates here given are necessarily of a most tentative character, they have been made on a basis sufficiently liberal to indicate that a sum considerably below the estimated cost of constructing a canal from Calumet to the sanitary canal would suffice for the construction and annual maintenance of a modern sand-filtration plant in connection with the 68th Street pumping station. The installation of a sand filter would possess the additional advantage that the incidental and accidental pollution of the lake would then be securely guarded against. On the other hand, it would prove most discouraging to discover after the expenditure of seven or eight million dollars for the construction of a drainage canal for the Calumet region that the pollution of the Hyde Park water supply from towns in Indiana south of the Calumet and from other sources was still so great that the amount of typhoid fever in that portion of the community served by this supply remained excessive.

It might be added, furthermore, that the amount of

water pumped by the 68th Street pumping station in 1900 was nearly one-fifth of the total pumped for the whole city, and that the average daily consumption of water for the whole city reached the enormous figure of 169 gallons per capita (average amount of water pumped per day in gallons, 322,599,630; population of Chicago, U. S. Census, 1,698,575). These figures betray the enormous waste of water that takes place under existing conditions. Experts insist that 70 gallons of water daily per capita amply suffices for all the legitimate needs of a modern American city.¹⁷ If it is true, as maintained by competent engineers, that more than one-half of the water pumped into the Chicago mains is wasted by leakage or carelessness, any method of reducing this waste would also reduce proportionately the cost of construction and maintenance of a sand filter, since both initial and operating expenses depend directly on the quantity of water treated.

It may be remarked finally that, assuming a reduction of one-third in the amount of water consumed (i. e., to 125 gallons daily per capita, which is still 50 per cent. larger than a liberal normal consumption), and assuming that the expense of construction of sand filters in other portions of the city would not differ greatly from the figures already given, the cost of installing a filtration plant for the water supply of the whole city would be about \$8,500,000, and the cost of operation should be capitalized at about the same sum.* This is certainly not the psychologic moment for inviting the citizens of Chicago to consider any general sanitary project, but so far as the Hyde Park water supply is concerned the construction of a sand filter in lieu of another drainage canal would seem worthy of consideration on grounds both of efficiency and economy.

*The construction of the Main Drainage Canal alone cost something more than \$36,000,000. Other changes and appurtenances are contemplated which will add materially to this sum. One recent estimate of the expense of further improvements is as follows:

For widening the Chicago river to a width of 130 feet between Lake and Eighteenth Streets, and to a width of 400 feet south of that point.....	\$11,000,000
For the widening of the earth section of the drainage channel between Chicago and Summit to the standard width of rock sections.....	500,000
For the construction of twenty-seven bascule bridges to replace center pier structures.....	4,050,000
For a system of drainage for Evanston and adjacent north shore towns.....	4,500,000
For a system of drainage for the Calumet region, including the construction of the Sag cut-off.....	11,879,854
Total.....	\$31,929,854
Add original cost of construction.....	36,000,000
	\$67,929,854

THE SURGICAL TREATMENT OF GALLSTONES.

J. F. W. ROSS, M.D., C.M.
TORONTO.

The treatment of gallstones can be divided into medical and surgical. For many years the medical treatment prevailed and the greater benefits to be obtained by surgical treatment were not duly appreciated. Owing to the great advances made in surgery the tables have been turned and the sufferers from gallstones obtain a much greater measure of relief. I know but little of the so-called medical treatment of gallstones, and I am very skeptical as to its practical value.

DANGERS INCURRED BY PATIENTS SUFFERING FROM GALLSTONES.

Not only is there a danger of sudden death from the passage of a gallstone, but there are many other dangers to be encountered. There is the great danger of gangrene of the gall bladder (closely resembling gangrene of the vermiform appendix), with rupture and death or with the formation of a secondary abscess; there is the danger of inflammation with empyema of the gall bladder, accompanied by chills, high fever and the occurrence of a suppurative pyelophlebitis followed by death. There is the danger that septic infection may travel from some ulcer produced by gallstone irritation of the mucous membrane of the gall bladder or ducts to the vessels of the liver. Even when no pus is to be found either in the gall bladder or gall ducts these septic conditions may spread beyond the confines of the gall bladder and produce inflammation of the peritoneum and surrounding structures. Abscesses may form external to the gall bladder and may perforate in various directions, upwards to the right pleural cavity, forwards through the skin or backwards into the posterior hepatic pouch. These are grave conditions, and if they do not terminate fatally the patient is liable to be ill for many weeks.

I have seen one patient die from shock produced by the passage of a gallstone through the common bile duct, and, a few years ago, I saw a gallstone that was presented to one of our medical societies after it had been removed postmortem from the common bile duct of a patient who died suddenly from shock during its attempted passage. Many other cases of death from this cause have been reported. Obstruction of the common bile duct by stone frequently occurs in patients advanced in years, so that this serious complication must be considered as a constant menace to those who are suffering from cholelithiasis.

A few weeks ago I removed a gallstone from the common bile duct of a woman aged 65, who was suffering for the first time from continued jaundice and who did not know that she was troubled with gallstones, though 147 were removed from the gall bladder. A more frequent resort to surgical treatment would prevent the occurrence of this serious condition in elderly people and would also prevent that slow and living death that is to be looked forward to by many of these sufferers. They begin to have fever and chills and intermittent attacks of jaundice with impairment of the appetite and a loss of strength. The excessive use of opiates and alcoholic stimulants makes them still more miserable until death finally ends the scene.

A patient suffering from gallstones may, at any moment, become seriously ill and the surgeon will find himself face to face with as great a responsibility as if he was dealing with a case of acute appendicitis. At any time these patients may have a violent outbreak of a

rapidly fatal cholecystitis with cholangitis. Repeated inflammations may produce such a condition of chronic inflammatory exudate as to prevent the surgeon from carrying out surgical measures for their relief. When brought face to face with these serious complications our responsibilities are increased.

GENERAL CONSIDERATIONS.

In discussing the surgery of the region occupied by gallstones we must consider the organs with which we have to deal. Stones may find a lodgment in the ducts throughout any part of their course, or in the gall bladder, or in both. When removing these stones we are called on to open hollow organs that are liable to leak, to peel away tissues from a solid organ that is liable to bleed, and to readily absorb septic material, and we are called on to open ducts that are lying in close proximity to blood vessels that may be injured. The leakage of bile from open ducts and from an opened gall bladder was to be feared before attention was drawn by Morison to the post-hepatic pouch and to the safety of gauze drainage by my friend, Dr. W. E. B. Davis, Birmingham, Ala., after he had demonstrated its usefulness in many experiments on dogs.

Morison's pouch should be used for drainage in all cases in which post-operative leakage is liable to occur. The method I have adopted is to institute through-and-through drainage by means of a piece of rubber tubing entering through the wound in front and emerging through a counter opening at the deepest part of this pouch. Not only should a rubber drainage tube be used, but iodoform gauze packing should be placed over the leaking point or points to still further assist the tube. With a due attention to this matter many of the operations for the removal of gallstones are robbed of their terrors and patients who formerly would have died can now be carried safely through.

Owing to the introduction of this method of drainage it is no longer necessary to break up calculi by the needling process, or to open the intestine for the purpose of removing a stone from the common duct, and why? Because we no longer are afraid to make a direct incision over the stone into even the most friable duct. Then, if necessary, we can readily break up the stone by means of gallstone forceps passed through the opening.

CHOLECYSTOSTOMY.

Gallstones are found most frequently in the gall bladder. They are sometimes formed with great rapidity. Among my collection I have several thousand taken from the gall bladder of one patient.

CASE 1.—In February, 1897, he had his first attack. Cholecystostomy was performed, a fistulous opening remained, and this was closed by two sutures. In November, 1897, he again had colic and jaundice; in March, 1898, Dr. Tiffany of Baltimore operated on him. He found no stones. In June, 1898, he was still in the hospital suffering from attacks of colic and transient jaundice. The gall bladder was again opened, but no stones were found. July 3 he suffered from a blow on the head for which a portion of the skull was elevated. In August, 1899, his colicky pains returned. October 1 he had colic for four days and was then jaundiced for two months. In November he was operated on again, for the fourth time, and black tarry fluid and one gallstone, soft and black and of the size of a cherry pit, were found in the gall bladder. A cholecystenterostomy was then performed and anastomosis with the colon completed. At last reports the button had not passed. The subsequent progress of the case is unknown to me. The gallstones in this case were like grains of gunpowder, and it was not to be expected that operative procedures would give much relief.

But this is an exceptional case, and it is a well-known fact that a simple cholecystostomy in a large majority of cases gives complete relief. The larger the stone, or stones, the greater the freedom from recurrences; the smaller the stones, the greater the liability to recurrences.

GANGRENE OF THE GALL BLADDER.

While it is a well-known fact that gallstones may lie in the gall bladder for years without giving rise to trouble, it is also well known that they will frequently produce a condition of inflammation of the gall bladder that may even suddenly eventuate in gangrene. I have met two cases of gangrene of the gall bladder.

CASE 2.—Dr. R., aged 62, was taken suddenly ill with severe pain in the abdomen. The bowels moved after the administration of a purgative. Temperature and pulse were elevated. Nausea. Some few years before he had had a severe attack of what was supposed to be typhoid fever, after which he suffered from terrible pains that were supposed to be due to indigestion. On examination of the abdomen fulness was felt below the edge of the liver. There was no rigidity of the right rectus muscle. Notwithstanding this fact the case was diagnosed as one of appendicitis. On opening the abdomen the appendix was found to be healthy. On looking further up a gangrenous gall bladder was seen snugly placed among inflamed intestines and omentum. The incision was enlarged, these adhesions were broken down readily, the gall bladder was opened and drained. The fluid evacuated was mucopurulent. Five gallstones were removed, one of them obstructing the cystic duct. A long glass drainage tube was placed to the bottom of Morison's pouch. Patient made an uninterrupted recovery.

CASE 3.—Mrs. W., who had a baby a month old, was taken suddenly ill early in the morning with severe pain in the abdomen. Her physician, Dr. T. B. Richardson, was sent for and he found her in great agony, and immediately administered a large dose of morphia. He was afraid that she would scarcely survive. Pulse was rapid and thready and the patient looked very ill. Improvement took place, but, later in the day, the pulse began to fail and he was again alarmed at her condition. I was sent for, but as I was out of town he decided to wait until the next day. In the morning the patient had somewhat improved. The temperature still remained high, having risen to 104 at the onset of the illness. She complained of one tender spot beneath the edge of the liver over the region of the gall bladder. There was slight puffing of the abdomen and vomiting. When I saw the patient the pulse was rapid and she was profoundly septic. A hard, tender, resistant spot could be made out over the region of the gall bladder, and I concluded that this must be another case of gangrene of the gall bladder. In order to share the responsibility I asked for another consultant before proceeding to operate. Very little hope was held out of the patient's recovery even with operation, owing to the septic condition. The abdomen was opened, the tense gall bladder was found, a large, green gangrenous patch involving at least one-third of its entire surface. The gall bladder contents were evacuated. The parts were too friable, swollen and thickened to permit of removal and on this account through-and-through drainage was established and the gall bladder area was packed off from the rest of the abdominal cavity by means of a large packing of iodoform gauze. During the convalescence it was necessary to again administer chloroform to remove the gauze, but the patient made an uninterrupted recovery. During the hurried manipulations, hurried owing to the patient's collapsed condition, no gallstone could be found.

It should be remembered that as the tender spot an inch and one-half from the anterior superior spine of the ilium towards the umbilicus points to appendicitis, so the tender spot an inch and one-half to the right and one inch and one-half above the umbilicus points to cholecystitis. Cholecystostomy was performed for the relief of this condition and was accompanied in the one case

by gauze drainage and in the other by tube drainage with recovery in each. Gallstones do not necessarily produce such severe inflammation as to lead to gangrene.

EMPHYEMA OF THE GALL BLADDER WITH GALLSTONES.

The next condition of which I wish to speak is that of empyema of the gall bladder. Inflammation has taken place and pus has been formed. The patient may be very ill in the acute septic condition, or may be in fair health while the gall bladder may be filled with pus that is almost sterile, as it is found to be in other situations in which it has been retained for a considerable time.

It has been stated that it is necessary and wise in this condition, as well as in that of gangrene of the bladder, to remove the entire organ. I consider that this is too sweeping an assertion. It is not necessary to remove the gall bladder in cases in which it is inflamed and septic and thickened from chronic inflammation and filled with pus. After it has been drained for a time and the offending calculi have been removed, the organ soon resumes its normal condition. I have considered it advisable, under such circumstances, to carry out intermittent irrigation of the organ by means of a small catheter placed in the gall bladder and attached to a douche tin. It is, as a rule, easy to fasten such a gall bladder to the abdominal wall owing to the fact that it has been considerably distended. Suppuration may be found in a gall bladder containing a few or many stones and with or without complete obstruction of the cystic duct.

CHRONIC INFLAMMATION OF THE GALL BLADDER CONTAINING CALCULI BUT NO PUS.

In these cases it is usual to find the gall bladder thickened, adherent, contracted and sometimes sacculated. There is evidence that the patient has suffered from many attacks of inflammation. The operation of cholecystostomy may be a very difficult one to perform, under the circumstances. If such a gall bladder is put on the stretch and fastened to the edges of the parietal incision it is liable to tear away. If stitched up and dropped back after the stones have been removed, the stitches are liable to tear out and permit of leakage, as it frequently happens that there is a partial obstruction to the flow of bile through the common duct. The operation of cholecystectomy, under the circumstances, would be a very difficult procedure. If sacculi are present it may be necessary to incise them individually and remove their contents and then to close the opening in a "sort of a way." Such closures can not be depended on to be water tight. I have treated such cases by passing a drainage tube into the gall bladder and stitching the opening in the gall bladder firmly around the outer wall of the tube. None of the stitches go through the tube. Gauze packing is then placed around the tube and another drain is either put into the bottom of Morison's pouch or carried through a counter opening at its lowest point. The gauze is removed about the fifth day and the tube in the gall bladder is removed about the same time. If a counter opening has been made in the flank this is not allowed to close for a couple of weeks. These cases may be very successfully dealt with in this manner.

CHOLECYSTECTOMY.

When a stone becomes blocked in the cystic duct the bile remaining in the gall bladder is decolorized after a time and nothing will then be left but a clear mucoid fluid. The gall bladder may become thinner and may remain freely movable below the costal margin on the

right side. While in this condition it may be so over-distended at any time as to become gangrenous, the gangrene usually beginning at its tip.

I operated on one such case where a sudden onset of pain and a tenderness on pressure over the gall bladder drew attention to the urgency of the condition. At the operation a very small gangrenous area could be made out at the end of the overdistended gall bladder. It is therefore advisable that all such cases should be operated on and the patient relieved from this source of danger.

The operation that should be performed, under the circumstances, is cholecystectomy; the entire gall bladder should be removed. This procedure can be carried out without difficulty. The tissues attached to the liver may be raised up with forceps and the finger can then be thrust into the layers of cellular tissue. Scissors will be required to cut through the peritoneum where it is dense. There is no hemorrhage to alarm the operator. The gall bladder is peeled off from the liver until the stone is reached; the duct is then further isolated beyond the stone and tied off with a fine silk ligature. Supporting sutures are placed over the end of the duct to bring peritoneum to peritoneum and act as an additional safeguard against a leak. It is wise to place a small strip of iodoform gauze down from the abdominal wound to the end of the cystic duct. Unless the operation of cholecystectomy is performed for this condition a mucous fistula may persist, and this may require a second operation for its relief. This secondary operation is a difficult one to perform owing to the fact that strong adhesions are now present. I met with these difficulties in one case, and for a few days after the operation despaired of the patient's life.

All operators seem to be agreed that it is wise to perform the operation of cholecystectomy in all cases in which we have a much distended and atrophied gall bladder with an occluded cystic duct. On one occasion I left three stones lying side by side in the cystic duct after having removed a large number from the gall bladder by cholecystostomy. The stones passed on without difficulty and the patient made an uninterrupted recovery. At the present time I would not allow the patient to run any such risk, but would remove the gall bladder and the cystic duct with the stones *in situ*. It was interesting to note in this case that when one stone had entered the duct other smaller stones followed.

I removed a gall bladder two weeks ago with the stone in the cystic duct. The undilated duct could be seen beyond the stone. After looking at the enormous distension it was easy to understand how stricture of the duct may be produced after the removal of the foreign body. The patient from whom this was removed made an easy recovery and the operation only consumed a few minutes.

The other indications for cholecystectomy are at present being discussed by the surgical world. Many surgeons consider that the gall bladder should always be removed for the conditions above mentioned, namely, gangrene of the gall bladder, empyema of the gall bladder, chronic inflammation and thickening of the gall bladder with or without contraction, and for cystic enlargement of the gall bladder. Others consider that this is too radical a procedure; that it is not necessary nor advisable, and that it is undoubtedly accompanied by a greater mortality than the operation of cholecystostomy. I feel satisfied that there is a danger that the pendulum may again swing, as it ever swings in the surgical world, too far toward the radical side, but to come back again, no doubt, in the course of time.

Let us for an instant consider the two analogous conditions, gangrene of the gall bladder with one or more stones in its interior, and gangrene of the vermiform appendix with one or more coproliths in its interior. Do we consider that it is always wise to remove a gangrenous appendix? Certainly not. There are times when we consider it wiser and safer to make our incision, to institute drainage and endeavor to isolate, with protecting gauze, the infected area. To dig down into and stir about these septic, infiltrated structures, under certain circumstances, is not good surgery. The same applies to the treatment of gangrenous conditions of the gall bladder. If, however, the organ can be readily removed and the tissues are not too friable to hold ligatures, it may be advisable to remove the offending organ, but, in my experience with two cases, the patient has not been in any condition to undergo such a prolonged operation.

Cholecystectomy does not produce a more radical cure than cholecystostomy. Even after cholecystectomy has been performed gallstones may form in the ducts in the liver itself and may be passed onward through them into the intestines. Owing to the fact that there is no cholecystitis to be encountered they are not large. I have seen, on one occasion, gallstones of medium size lying in a row in the hepatic duct above the junction of the hepatic and cystic ducts.

Langenbeck has denied that obstruction can result from stones forming in the biliary ducts outside of the gall bladder, but, as I have just said, I have seen such obstruction. The smallest stone in the row was nearest the liver. I was able to milk the stones down the hepatic duct and up from the common duct through the cystic duct into the gall bladder. The gall bladder had been opened and the gallstones were all removed in this manner.

The gall bladder is not known to be of any particular value and many animals are able to get along without it. It is occasionally found wanting in the human species. It has been said that the hemorrhagic condition of the mucous membrane of the gall bladder that is likely to occur as a post-operative complication after removal of gallstones, may be done away with by removal of the organ at the time of operation. Such hemorrhagic conditions are, however, rare. I have met with but one case, and at the postmortem examination it was found that the blood had come from a ruptured vessel in the liver, and, therefore, cholecystectomy would not have prevented death.

It has been stated as further argument in favor of cholecystectomy that by the removal of the gall bladder there is no danger of a recurrence of the cholecystitis, the disturbing element. I have not seen such disturbance occur after simple cholecystostomy and drainage if the stones have been thoroughly removed. It may always be desirable to remove the gall bladder for all the diseases to which it is liable, but the question to be answered is, is it always wise to do so?

In the presence of obstructive jaundice the operation of cholecystectomy is not advisable. The common duct being already obstructed it is desirable either to remove the stone and rely on the future patency of the duct for the relief of the patient, or to remove the stone and anastomose the gall bladder to the intestine, or to leave the stone *in situ* and perform cholecystenterostomy. It must be more difficult to anastomose the common duct itself than to anastomose the gall bladder to the intestine.

It has been stated that cholecystectomy should be con-

sidered as a curative operation, as it removes the cause of the disease. From what I have already stated I am satisfied that this is not so. Having seen large stones in the hepatic duct and in abscesses of the liver I am convinced that quite large stones may form outside of the gall bladder. There must, therefore, still be a danger of obstruction of the ducts even after the gall bladder has been removed. It would be interesting to ascertain whether the animals possessing no gall bladder suffer from gallstones.

A great deal has been said regarding the fistulæ that are left after cholecystostomy. They are not comfortable, but are undoubtedly curative, and, in the large majority of cases, they close without trouble. The only fistula that is troublesome is the mucous fistula, and, as we have already decided that the gall bladder should be removed in the cases in which the mucous fistula is liable to form, this difficulty is done away with. The fistula that forms owing to the fact that the common duct is still obstructed is a useful one, for without it the patient must undoubtedly continue to suffer from jaundice; and if it persists after having fulfilled its offices it may be done away with by making an anastomosis when the patient is in a greatly improved condition. So that we see the discomfiture to the surgeon and the discomfort of the patient have been blessings in disguise.

The formation of fistulæ teaches us that we should not use a large drainage tube for the purpose of draining the gall bladder. In this way the gall bladder opening can be reduced in size and the opening will close more quickly. Any suture used to fasten the gall bladder to the skin or the abdominal wound should be a continuous one, if non-absorbable, and it should be removed in a few days after operation. The drainage tube should be removed early except in cases of empyema of the gall bladder.

The argument that is used for the removal of the gall bladder in all cases owing to the fact that cancer is liable to supervene on gallstone irritation, is not based on a sure foundation. The surgeon does not propose to leave gallstones in the gall bladder to give rise to the irritation that is to lead up to the cancer, so that with or without a gall bladder this danger will be done away with.

The flow of bile into the gall bladder is greatest at night. It has never been demonstrated that patients from whom the gall bladder has been removed suffer in the slightest degree as a consequence of this fact.

CHOLECYSTENTEROSTOMY.

The operation of cholecystenterostomy can be performed by means of the elastic ligature or the Murphy button. I have used both and prefer the button. When the button is used care must be taken to allow long threads to float from the portion of the button placed in the intestine into the lumen of the gut. These silk threads become entangled in the fecal matter and the slight extra traction that is exerted has a tendency to draw the button toward the intestine and away from the gall bladder. I used the smallest sized Murphy button that I could buy and then had some very small ones, that I show here, made to order by Truax, Greene & Co. These have been used with perfect satisfaction to myself and to the patients.

After the bile has been diverted through the new channel the concretion impacted in the common duct grows smaller and disintegrates. I believe that it is quite possible that it may entirely disappear and that the bile may again proceed by the normal channel.

The reverse of this is the case so long as the bile is passing by the impacted calculus, owing to the fact that more bilirubin calcium is being precipitated on its surface until it may increase to a very great extent.

CHOLEDOCHOLITHECTOMY.

We have considered the treatment of stones in the gall bladder and in the cystic duct. We have now to turn our attention to the treatment of gallstones in the common or hepatic ducts. It is seldom that stones are met with in the hepatic duct. When they are met with they must be removed by pressing them down into the common duct, from which they may be removed by forcing them back through the cystic duct into the gall bladder, or they must be removed by direct incision. When a stone is lodged in the common duct it will be accompanied by an intermittent jaundice or a jaundice of varying intensity. The patient may be very deeply jaundiced for a great length of time.

The operation for the removal of the stone is in some cases fraught with such risk to the life and difficulty to the surgeon that it may be advisable to adopt another measure for the relief of the patient. An anastomosis between the gall bladder and intestine may be established. The colon is the portion of the bowel that can be most readily approximated to the gall bladder. Before this operation was carried out it was supposed that it was not advisable or, in other words, that the small intestine should be used instead. I have found that the patients do not have diarrhea as a consequence of the pouring of the bile into the large intestine or any digestive disturbances. When the small intestine is used it must be either drawn up over the colon or taken through the folds of its mesentery. I have anastomosed the gall bladder to the large intestine on several occasions with the most perfect results.

Owing to the advances that have been made in gall-bladder surgery cholecystenterostomy stands to-day in a different position. We can now incise ducts with impunity that can not, owing to their friability, be stitched, owing to the fact that we understand the safety given by careful and through drainage. The operation of cholecystenterostomy must now be recorded as rather a makeshift, only to be used when a patient is in a very bad condition.

On one occasion, when operating on a young woman, I found that she already had an anastomotic opening between the gall bladder and intestine that had been produced by the bursting of an inflamed gall bladder into the bowel.

It has been stated that the relations of the hepatic artery, the portal vein and the common duct may be changed and one of the vessels may run across the duct. If the positions of these important structures are altered the removal of a stone from the common bile duct is surrounded by a new and terrible danger. The condition might be detected during operation by a careful preliminary examination of the parts. Even when the structures are normally placed the operation is a difficult one. Much assistance can be attained by a forceps that I have had made by Stevens & Sons of Toronto. It is intended to replace the fingers of the left hand, to grasp the duct containing the stone and to draw it forwards to be within easier reach and away from the important structures beneath it.

The difficulty of the operation varies with the construction of the patient. It is more difficult to perform the operation on a patient with deep ribs than on one with short ribs. In all cases a large sandbag placed under the back and the transverse oblique incision should

be employed, taking care to keep the incision well down below the hepatic margin. The liver can then be pulled upwards and the stomach inwards and downwards and the colon downwards so that the field of operation may be brought well into view. It is always advisable to pack in sponges to drag down the stomach and intestines and to protect the general peritoneal cavity from infection. I find that this dragging down of the stomach is of great assistance.

If the forceps I have mentioned are not used the duct must be held forwards with the thumb and index finger or the first two fingers of the left hand. With the duct held down either by the fingers or the rollers of the forceps the operator must decide on the length of the incision into the duct that will be necessary for the removal of a stone. A large stone may be crushed and the debris can be removed with a small scoop. When the length of the incision into the duct has been decided on a purse-string suture should be placed beyond its limits, the incision must then be made in the center of the oval formed by the running suture. The stone having been removed and a probe having been passed through the common duct into the intestine the purse-string suture is drawn and tied and any further escape of bile over the field of operation is prevented. A supporting row of mattress sutures should now be placed to more securely close the opening into the duct. Before closing the abdomen it will be wise to place a small gauze drain down to the duct and to drain Morison's pouch by a single drainage tube from the front or by through-and-through drainage.

As I have said before, the intestine should not be opened for the purpose of removing a stone from the common bile duct. Such a procedure is not necessary according to the light of our more recent experience. It may happen that a malignant growth, a so-called cylindroma, obstructing the common bile duct is mistaken for an impacted gallstone. I have met with such a case in my own practice and have seen two similar cases in the practice of others. Under such circumstances the jaundice usually comes on suddenly without pain; it may be intermittent. A rounded mass will be felt after the abdomen has been opened that can only be differentiated from stone by means of a needle passed through the wall of the duct into the mass, or by means of the passage of a probe or a pair of forceps through an incision into the duct. Owing to its gritty nature a gallstone can be easily distinguished from a neoplasm. These growths are always rounded and not faceted and frequently move back and forth in the duct through a small space.

It is scarcely necessary for me to enter into a description of more than general details of these operations to such an audience. We all know that these operations can not be carried out successfully unless proper precautions are taken to prevent contamination of the peritoneal cavity. Sponges, absolutely sterile and plenty of them, must be made use of so that during the performance of the work all the intestines, except a portion of the colon and the stomach, are kept out of view. Sponges soiled with bile or gall-bladder mucus must be discarded and not used again during the performance of the operation.

And now, in conclusion, let me say that there are two great surgical principles involved in this work; firstly, thorough asepsis and thorough protection against the infection of any of the surrounding tissues; and, secondly, thorough and efficient drainage. If these two principles are kept in mind the operator can sacrifice

thoroughness in his work for the sake of the benefit of haste to his patient. Many of these patients do not withstand the shock of a prolonged operation and the length of time occupied is of great importance. In the pelvis we have been endeavoring to do away with drainage while in this region we provide the most thorough drainage. The conditions are different.

RECENT INVESTIGATIONS CONCERNING THE RELATION OF HUMAN AND BOVINE TUBERCULOSIS.*

D. E. SALMON, D.V.M.

CHIEF OF THE U. S. BUREAU OF ANIMAL INDUSTRY.
WASHINGTON, D.C.

During the past year the question of the relation of bovine and human tuberculosis has been discussed by numerous investigators who have brought forward new facts and deductions and thrown much light on the subject. There has undoubtedly been greater activity in pressing the researches relative to this subject than at any other time in the history of medicine. The conclusions presented by Koch¹ at the British Congress on Tuberculosis were so unexpected and so different from the views of the majority of investigators that they have stimulated research, and in that way, far more than by any presentation of facts, have aided in elucidating the question.

THE INOCULATION OF MONKEYS.

One of the first lines of investigation which suggested itself as a means of throwing light on the transmission of bovine tuberculosis to man was the inoculation of monkeys. These animals being more closely related to man than any others, it was to be supposed that if man was immune to bovine tuberculosis, monkeys, if not immune, would at least show a certain degree of insusceptibility. The experiments of De Jong and of the Bureau of Animal Industry show that bovine bacilli are at least as virulent for monkeys as are human bacilli. Comparative tests have also been made under the direction of the Bureau of Animal Industry with tuberculin made from human and bovine bacilli, and it has been found that both varieties of tuberculin produce a reaction in tubercular cattle and also in tubercular people. These indirect experiments indicate, therefore, so far as they go, the near relation of human and bovine tuberculosis and the susceptibility of man to the bovine bacilli.

TRANSMISSION FROM MAN TO CATTLE.

A review of the older literature of the subject indicates very clearly that both Martin² and Chauveau³ produced tuberculosis in cattle in ingestion and inoculation experiments by the use of sputum and other tubercular material from man. More recently Arloing, De Jong and Ravenel have each produced tuberculosis in cattle by inoculation with tubercle bacilli obtained from the human subject. These experiments appear to be free from objectionable features, and it seems logical to conclude from them that while the human bacillus is less virulent than the bovine bacillus, the bacilli from different cases vary in activity and are sometimes able to produce a fatal tuberculosis in cattle. There are, consequently, no longer any grounds for the argument that bovine tuberculosis is not communicable to man because human tuberculosis is not communicable to cattle.

INFECTION OF MAN FROM CATTLE.

Considerable light has also been thrown on the question of the transmission of bovine tuberculosis to man. Ravenel⁴ has reported four cases of direct inoculation of man with bovine bacillus, which occurred in Pennsylvania, and in which tubercular lesions developed at the point of inoculation. The writer⁵ has recorded a similar case reported to him by Naughton, which occurred in one of the Chicago abattoirs, and reviewed in a report to the American Public Health Association⁶ the cases of similar transmission which appeared to be most carefully observed and reasonably free from doubt. Ravenel has reported the inoculation of one of his assistants with the bovine bacillus which multiplied locally, produced a lesion at the point of entrance, and was recovered fifty-eight days after inoculation. The bacillus had apparently retained its original virulence during this period. Ravenel has also obtained a bacillus from an intestinal lesion of a child, which, when inoculated on cattle, apparently has all the virulence of the bacillus from bovine sources.⁷ Taking this in connection with the bacilli obtained from human lesions by Vagedes⁸ and Lartigau,⁹ which had the cultural peculiarities and virulence of the bovine bacilli, and it would appear that bovine bacilli, or others not distinguishable from them, have certainly been obtained from human tissues, where they had been multiplying and where they had produced disease. These investigations apparently answer in the affirmative the question that has been raised as to whether bovine tuberculosis is transmissible to man.

The frequency with which man is infected with animal tuberculosis can not be determined by the data now available, and the investigation of this question is surrounded with many difficulties. It has been made clear that we have no right to demand a primary lesion in the intestine as the criterion of ingestion tuberculosis. In experimental animals fed on tubercular material the oldest lesions are frequently found in the glands of the head and neck or even in the bronchial glands and lungs. While tubercle bacilli may pass through the stomach and penetrate the intestinal wall, this apparently is not the most common channel of infection from tubercular food. There are some authors who believe that even in inhalation tuberculosis the bacilli enter the tissues from the nasopharynx or pharynx, and seldom if ever follow the lumen of the air channels beyond the larynx. Now the pharynx, and probably also the nasopharynx, is as easily contaminated by infected food as by inhaled bacilli. It is difficult, therefore, to see how we can expect anything in the distribution of the lesions which will enable us to distinguish between ingestion and inhalation tuberculosis.

VARIATION IN THE BACILLI.

Probably the isolation of the bacilli from the lesions in man and the determination of their virulence will give some idea as to the frequency of bovine infection, but we must expect that in many cases the bacilli will be modified to such an extent that their source can no longer be determined. Ravenel¹⁰ infected pigs with the human bacillus, and on recovering it from these animals found that it had increased very much in virulence. The writer asked Dr. Schroeder to carry out an experiment by injecting human bacilli into the milk ducts of an adult cow, the idea being to determine whether or not they would multiply in this situation and increase in virulence. The injection was made without injury to the tissues, and was followed by enlargement and in-

duration in the quarter of the udder into which the injection was made, which persisted for more than six months. During this time a thick, creamy pus was formed in the milk ducts, and inoculations were made with this from time to time. The bacilli in this case appeared to lose their virulence, and as the period of their existence in the udder increased they required a longer time to kill guinea-pigs than at the time the infection was made. Later they appeared to have regained a part of the virulence which they had lost. It may be added further that the effect of this culture was far more persistent than that of dead bacilli injected in a similar manner. In the latter case an enlargement and induration of the quarter of the udder operated on occurred to almost the same degree as with the living bacilli, but the effect was transitory and disappeared in a few weeks. The experiments of Ravenel and of Schroeder therefore confirm many other observations which have been made relative to the instability of the virulence of tubercle bacilli.

The rapid modifications which these germs may undergo are shown by the increasing facility of culture after they have been grown a time in the laboratory, by the great variation in biological characters when inoculated into cold-blooded animals, as shown by Dubard,¹¹ and by the researches of Nocard and others in transforming mammalian bacillus into a stock having the characters of the avian, and vice versa. With these examples of the variability of the bovine bacillus before us, it is impossible to admit that the bovine bacillus, when it infects mankind, should always be recovered with its original morphological characters and cultural peculiarities. It would appear that it may retain these in certain cases and in others it may lose them.

STATISTICS OF TUBERCULOSIS AMONG CHILDREN WHO TAKE COW'S MILK.

It has appeared to me that we might obtain some indications from statistics as to the frequency of human infection from animal sources. While not losing sight of the fact that pulmonary tuberculosis may be caused by ingestion as well as by inhalation of the bacilli, we may nevertheless admit that by far the greater number of cases of pulmonary tuberculosis are the result of infection by inhalation. This being the case, we should expect to find a difference in the rate of increase or decrease of tuberculosis of the lungs as compared with other forms of tuberculosis.

Thorne's table¹² is as interesting and instructive now as it was when he published it in 1898, and notwithstanding the critical examination of the subject which has since taken place, the bearing of it appears plain and incontestable. This table shows that in England and Wales between the periods 1851-1860 and 1891-1895 there was a reduction of the mortality at all ages from phthisis or pulmonary tuberculosis of 45.4 per cent., while the reduction of the mortality at all ages from tabes mesenterica or abdominal tuberculosis was but 8.5 per cent., or less than one-fifth as much. And what is more remarkable, the mortality from tabes mesenterica in children under one year of age actually increased 27.7 per cent. for the period referred to.

Some years ago a publication was issued by the State Board of Health of Massachusetts entitled "The Vital Statistics of Massachusetts, 1856-1895." In this compilation the two years 1856-57 was contrasted with the two years 1894-95. In the two years first mentioned, for the period under five years of age, there were 46.3 deaths from pulmonary phthisis to 1,000 deaths from all causes. In the two years last mentioned there were

but 15.6 deaths from pulmonary phthisis to 1,000 deaths from all causes, or one-third as many. This is a very gratifying reduction in the phthisis death rate. Let us see now how it is with other forms of tuberculosis. In the two years first mentioned there were in the same age class 70.7 deaths from other forms of tuberculosis to each 1,000 deaths from all causes; and in the two years last mentioned there were 96.2 deaths from other forms of tuberculosis to each 1,000 deaths from all causes. That is, in this forty years there appears to have been an increase of 36 per cent. in the forms of tuberculosis other than phthisis in the class under five years of age, while there was a reduction in the mortality from phthisis at all ages of about 45 per cent. Are these statistics worthless or do they mean something?

I have also examined the statistics of Michigan, and I find that in that state during the years 1870 to 1884, inclusive, taking the class under five years of age, there were for each 100 deaths from consumption 81.8 deaths from other forms of tuberculosis; during the years 1885 to 1897, inclusive, there were 104.3 deaths from other forms of tuberculosis to each 100 from consumption; while during the three years 1898 to 1900, inclusive, there were 263.3 deaths from other forms of tuberculosis to each 100 from consumption. Why this tremendous increase in the mortality from other forms of tuberculosis as compared with consumption at what has well been called the milk-drinking age of life?

Gottstein,¹³ in a recent study of this subject, concludes that among children in Berlin the mortality of those at the breast is but slightly more than half as much from tuberculosis as among those otherwise nourished, the proportion as he finds it being as 6 to 10. He also finds, in studying the statistics of 23 large cities and university cities, where the returns are especially reliable, that whereas there has been a reduction of the mortality at all ages from tuberculosis, this reduction has been distinctly less in children under 15 years of age than in persons over that age. From this he concludes that "the thought is not to be set aside that in the etiology of tuberculosis in children and in grown people very important differences must occur. There must be assumed for the infection of children another source than for that of grown people, and it certainly is natural to conclude from the difference established statistically that the source of children's tuberculosis is to be sought partly in nourishment with milk containing tubercle bacilli, while the decrease since 1894 is to be traced back to the better general and individual prophylaxis in the care of milk."

I have recently compiled a table showing the deaths per million population from different forms of tuberculosis, taking the last year for which returns are available. From this the deaths from *tabes mesenterica* or abdominal tuberculosis are, at all ages, as follows: New York City, 13; Chicago, 17; Boston, 32; Berlin, 40; Paris, 61; London, 221; England and Wales, 202; Scotland, 223; Ireland, 231. The great preponderance of this disease in Great Britain and Ireland is remarkable. On another occasion I endeavored to explain this partly by the different conditions existing in the countries covered by these statistics; that is, there is very much more tuberculosis in cattle in European countries than in the United States; there is far better protection by meat inspection in the United States and the continent of Europe than in Great Britain and Ireland, and there also appears to be more universal sterilization of milk on the continent.

EUROPEAN VS. AMERICAN CUSTOMS AS TO STERILIZATION OF MILK.

I have been interested in reading the opinion of Prof. H. W. Conn,¹⁴ written some years ago, with reference to this subject. In his report on "The present attitude of European science toward tuberculosis in cattle," which was prepared after visiting the different countries of Europe and studying the conditions there, he said:

"Furthermore, it is a fact that in most European countries milk is not drunk raw to any very appreciable extent. Nearly all of continental Europe has, in the last few years, acquired the habit of sterilizing the milk before using it. In some countries this is almost universal. In Switzerland the children are taught the danger of drinking milk without sterilizing, and at the present time the amount of milk drunk without some kind of preliminary heating is comparatively small in continental countries. On the other hand, in England and in the United States the habit of sterilizing milk has not obtained much foothold. While milk is sterilized frequently for use among infants and invalids, there is no such general custom as in Europe in this direction, and in these countries we may say that the great bulk of the milk is drunk without sterilization. Now if milk were a considerable source of tuberculosis it would be inevitable that we should find a difference in the statistical results from countries where milk is used raw, and those from countries where it is sterilized."

It is immaterial to our argument that Professor Conn failed to find the difference between the statistics of Great Britain and of the Continent which he thought should exist if milk were an infective agent. We know now that such a difference does exist fully as great as could be expected. What we are specially interested in is the reason for this difference.

The figures quoted appear to indicate a considerable number of cases of disease in man originating from contaminated food, but still it must be admitted that this evidence is indirect and not altogether trustworthy. It must be taken as an indication rather than as a positive demonstration. Considered with the other evidence that has been mentioned, it justifies us in assuming provisionally that there is considerable danger to human health from the ingestion of food containing living tubercle bacilli.

In conclusion, it appears that there is now sufficient evidence to prove that tubercle bacilli of human origin may infect cattle and produce a progressive and fatal disease in them; also, that tubercle bacilli from bovine sources may infect man and produce a progressive and fatal disease. Ingestion tuberculosis may have its starting-point in the glands of the neck or thorax, or even in the lungs, and the number of cases of human tuberculosis showing a primary intestinal lesion is no indication of the number of cases which occur from ingestion. We must depend largely on clinical evidence for a determination of the relative frequency with which man is infected by tubercular food.

THE INTERTRANSMISSIBILITY OF HUMAN AND BOVINE TUBERCULOSIS;

A REVIEW OF THE EXPERIMENTAL EVIDENCE.*

R. R. DINWIDDIE, M.D.

FAYETTEVILLE, ARK.

Within the past two years a number of articles have appeared beside that of to-day more or less exhaustively reviewing the evidence as to the frequency or possibility of human tuberculosis originating by contagion from cattle. Such evidence as we can obtain must necessarily be circumstantial. Even if it were permissible to make direct inoculation or infection experiments on the human being, a settlement of the question could only be obtained by a series of comparative tests on many individuals with tubercle bacilli of human and bovine origin respectively, and accompanied by all the safeguards to exact experimentation which have been found necessary in our similar tests made on cattle. We can therefore see the folly and the futility of those oversanguine experimenters who propose to decide the matter by one clumsily conducted inoculation test on a human victim. Truly, "Fools rush in where angels fear to tread."

Beside the experimental evidence—along with which I include that which is derived from a comparison of the biologic characters of the bacilli—we may obtain some information from other sources: from a comparative study of the naturally acquired disease in man and animal in reference to its contributory causes, its course, its anatomic and histologic features, and from the records of accidental inoculation or supposed ingestion infection of human beings from bovine tubercular products. This part of the subject having been already discussed I shall limit myself to a few remarks on certain points only which have come under my own observation.

CONTRIBUTORY CAUSES.

With the exception of certain minor influences which are not in operation in the lower animals, contributory causes are closely comparable in the human and bovine animals. In a recent paper¹ I have attempted to show that in human as in bovine tuberculosis by far the most important of these so-called auxiliary causes is the universally prevalent disregard of adequate ventilation requirements in sleeping rooms and stables. Above all other conditions tuberculosis is associated with overcrowding—among cattle practically confined to stabled herds; in human beings the special scourge of the tenement houses, infrequent or even unknown among races of primitive habits yet exempt from the insanitary vices of our modern civilization.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee: Drs. Arthur R. Reynolds, George Cook and Heman Spalding.

The course of the disease in cattle is not dissimilar from that of man. It is, as a rule, chronic, phthisis or pining, only showing itself as a late symptom. The number of animals showing any symptoms is only a small percentage of those actually infected. Recovery of individual cases under favorable conditions no doubt does occur, but on this point we have little knowledge. Latency or non-progressiveness appears to be as common a feature as in mankind.

THE BOVINE ANATOMIC LESIONS.

The anatomic lesions of the bovine disease are characterized by their predilection for the serous membranes, the magnitude of the tubercle conglomerates, their fibrous structure and tendency to calcareous deposits, and finally by the relative scarcity of tubercle bacilli. Ulcerative lung lesions are less common than in man, and for this reason the bronchial discharges are relatively less abundant and poorer in their content of tubercle bacilli. When pulmonary cavities or vomicae do occur in cattle, the discharge is as profuse and the numbers of tubercle bacilli as great as in advanced pulmonary phthisis of man. Moreover, the tubercle bacilli present in such specimens do not differ morphologically from those of human sputa. These facts I have been able to demonstrate from specimens of ulcerative lung disease in cattle obtained many years ago, and now on exhibition here. In regions not open to external infection, as in lymph nodes and on serous membranes, the necrotic tissues do not liquefy and become purulent, but appear either as tough coherent masses or as accumulations of unorganized debris of butter-like consistency in which tubercle bacilli are usually difficult of demonstration. Specimens illustrating these conditions may be seen in all museum collections of cattle tuberculosis.

In the records of accidental infection of mankind by bovine tubercular products either by inoculation or supposedly by ingestion in milk we have an important source of evidence as to the transmissibility of the disease. On account of the extreme prevalence of human tubercular disease and the impossibility of tracing the source of infection, it is obvious that this evidence, unless carefully weighed, may easily lead us astray. It also is really little better than circumstantial. I have nothing to add to the able reviews of this part of our subject which have recently appeared.

EVIDENCE FROM EXPERIMENT.

Experimental evidence as to the identity or otherwise of human and bovine tuberculosis is not of recent date only, for we find that inoculation and feeding tests of tubercular products from man and from cattle had been made on various species of animals long before the bacterial nature of the disease was demonstrated. In an earlier report² I have summarized the records of such of these experiments as admitted of comparison. Although these earlier infection tests were seldom designedly comparative, they nevertheless, when collectively reviewed, enabled us to recognize the same differences in the effects of the human and bovine virus which have recently been more clearly demonstrated by comparative infection tests with cultures. Nevertheless, the interpretation by different investigators of the results obtained in the past, has been no less contradictory than at the present day.

Such investigators as Chauveau,³ Klebs,⁴ Crookshank⁵ and others who have infected cattle with human tubercular virus have expressed the opinion that the resulting lesions are identical, anatomically and histologically,

with those of Perlsucht—the naturally acquired cattle disease.

Creighton,⁶ Pütz,⁷ Klein and Gibbes⁸ are among those who, from similar experiments, arrived at the opposite conclusion; namely, that there was not only a difference in virulence of human and bovine tubercle when inoculated in cattle, but a difference also in the kind (as well as degree) of the resulting lesions.

The structure of the new formations induced by such inoculations in different species of animals, can not well be studied apart from the extent of these lesions; consequently, in reviewing the more recent work in this line I shall consider these two features together.

Up to the date of Koch's memorable discovery of the bacilli of tuberculosis, apparently identical in man and cattle, there was, as we have seen, a difference of opinion among pathologists as to the identity of the disease in the two species. It had been repeatedly demonstrated, for instance, that the bovine tubercular virus produced by inoculation in the rabbit more extensive lesions than sputa derived from human consumptives. Furthermore, a critical study of infection tests made by different authors, such of them as admit of comparison, will show that this higher virulence of the bovine tubercle was exhibited also toward other animal species, and more especially toward cattle.

This fact not being clearly brought out by comparative tests made by any one investigator did not receive due recognition. Pütz (1884), however, as a result of his researches, makes the following statement: "A susceptibility of cattle for the tuberculosis poison of man, and of the latter for the Perlsucht poison of cattle is not shown by any observations which are entirely free from objections." In his own experiments the results were always negative in bringing about in calves a typical Perlsucht with human tubercular material, but positive in producing a local development of tubercles containing the specific bacilli—"lesions no more representative of the typical tuberculosis of cattle than are the vaccination pustules representative of variola proper."

Against this view may be placed that of Chauveau (1891), another investigator, who on several occasions had made comparative infection tests on cattle, and claims for his experiments the first complete experimental demonstration of the identity of the human and bovine disease. He states that "human tubercular virus reacts towards the bovine species exactly like tubercular virus coming from cattle."

With the discovery of the bacilli identical in their staining reactions in human and bovine tubercle, similar in cultural features, and in their effects on the guinea-pig, the etiologic identity of human tuberculosis and Perlsucht of cattle was generally conceded by pathologists, practically all writers on tuberculosis emphasizing more or less the dangers of human infection from the use of the milk of tuberculous cows. On the other hand, veterinary authors have generally assumed that the human consumptive may be a source of infection for the cow stable. It was with the view of testing this latter proposition that my own experiments in feeding calves with the expectorations of human consumptives were begun in 1896. In the same year was published the first report of Theobald Smith's inoculation experiments on cattle,⁹ the earliest comparative tests which had been made with cultures.

Frothingham¹⁰ (1897) made communication of his inoculation experiments on calves with tubercle bacilli cultures of human origin. In the following year a

further report¹¹ was made by Smith of more extensive experiments undertaken in conjunction with the Massachusetts cattle commissioners.

Although my own sputum infection experiments for the Arkansas Agricultural Station were commenced independently, I am glad to admit that my later tests with cultures were modified, if not suggested, by those of Theobald Smith, to whom undoubtedly belongs the priority in this as in many other important lines of investigation and achievement in comparative pathology. Referring briefly to these experiments of my own, they were undertaken in order to test, as I have said, the possibility or likelihood of tuberculosis of cattle, and especially of dairy cows, having its source in the expectorations of consumptive attendants. I need not emphasize the vast importance of exact knowledge on this question from the standpoint of agriculture as much as from that of public health.

My experiments included (1) feeding tests on cattle with human tubercular sputum, (2) comparative inoculation tests on cattle with human and bovine tubercle respectively, and (3) similar inoculation tests with artificial cultures of tubercle bacilli from these two sources on cattle, sheep and swine. About the same time Pearson and Ravenel, of the University of Pennsylvania, were engaged in similar investigations, their infection tests also embracing a number of different species of the domesticated animals. The report of this work has lately been published.¹²

Koch and Schütz of Berlin have furnished the latest contribution to this line of investigation in the address of the former¹³ at the British Tuberculosis Congress of last year (1901). Although no new facts were brought to light by their experiments, the results of which were merely confirmatory of those previously obtained by American investigators, this address, as is well known, attracted world-wide attention on account of the great scientific reputation of the author and the somewhat extreme interpretation which he placed on the results obtained.

During the last year numerous other experimenters have been stimulated to a repetition of these inoculation tests on cattle with human tubercle, and even human martyrs have offered themselves, and been accepted by over-sanguine investigators, for inoculations from the bovine. Already we read of results: Calves have been successfully killed by sputum inoculation and human beings successfully infected (and cured) after inoculations from cattle; but we may well postpone any review of the work of these over-hasty experimenters until their enthusiasm moderates.

The more extensive and accurate of these recent experiments, namely, in order of publication, those of Smith, Dinwiddie, Pearson and Ravenel, Koch and Schütz, although not all co-extensive in design, have been practically in agreement in their results. It is therefore unnecessary to review each of them separately, and the summary which I here present is mainly the results obtained in my own experiments.

Inoculation of artificial cultures of the bacilli of bovine tuberculosis into the peritoneal cavity induces in calves, sheep and swine a rapidly progressive disease, early extension to the thoracic organs and death within a few months. Cultures of human origin (sputum) similarly inoculated, occasion in cattle a local eruption of tubercles over the serosa, especially abundant on the free omentum and in the sulci between the coils of the large gut. A tuberculin reaction may be obtained two weeks after inoculation. Sometimes no reaction is ob-

tained, and in all my cases this reaction was absent four to five months after inoculation. The initial lesions are similar in kind to those produced by the bovine germ, the difference showing itself later by retrogressive instead of progressive changes. If killed within a few months there may be found in addition to the tubercles mentioned above, and now already calcareous, a greater or less formation of pendant fibrous fringes and small papular or pedunculated fibrous nodules outgrowing from various parts of the serous coating of the viscera. The abdominal lymph nodes may or may not be involved. If kept for a year or more before dissection all traces of earlier changes may have disappeared. This, at least, has been my experience, and I have seen no impairment of health in cattle as a result of such infection from the human. I should not, however, dispute the possibility of inducing fatal disease in these animals by such inoculations. If the initial changes above described be so excessive as to impair the recuperative power of the tissues or their resistance to further invasion, the animal may succumb in a short time, either from the magnitude of the local changes or from unchecked generalization of the bacilli. Very young or feeble experimental animals, unhygienic surroundings, intravenous inoculations or intraperitoneal inoculations of impure cultures, such as we find in sputum, are the conditions on which we might suppose such a result to depend.

In sheep, human tubercle bacilli produce similar results as in cattle, but the local lesions are more extensive and more persistent. Pigs exhibit a somewhat greater susceptibility and may contract a progressive disease from such inoculations.

Generalization of the bacilli by way of the blood stream occurs in cattle, sheep and pigs, with formations of incipient miliary tubercles, which later become abortive in development, and are found on dissection as minute white points throughout the lung or as calcareous seed-like encapsuled granules in lung or spleen. On the other hand, if in pigs there is a pre-existent or intercurrent pulmonary disease generalization is followed by changes similar to those induced by the bovine germ—progressive miliary tubercles with enormous multiplication of tubercle bacilli in the lung tissue or its morbid secretions. Inoculation of sputum instead of pure cultures may act in a similar manner by producing a mixed infection.

BIOLOGIC CHARACTERS OF THE BACILLI.

The remarks which I have to make under this heading are mainly derived from notes of rather hurried observations made during the progress of the inoculation experiments described in Bulletins 57 and 63 of the Arkansas Agricultural Experiment Station. They are somewhat fragmentary, but on the whole are in close agreement with the facts as observed and more fully described by Ravenel.

Tubercle bacilli, as has been frequently noted, present considerable variation in morphology under different conditions of growth. In sputum they may be long or short, straight or bent, granular or homogeneous in staining. A similar variability occurs in the bovine germ, and hence comparison is less exact than in species of more constant morphology. In general, bovine tubercle bacilli are shorter than those of man. In the caseous masses of tubercular lymph nodes in cattle the bacilli are usually rare, but occasionally I have found isolated collections of such material in which the bacilli were present in large numbers. In such of these speci-

mens as I have seen the bacilli are uniformly short, granular or solid in staining, and not thicker than the bacilli of sputum. In ulcerating lung disease of cattle, as we have seen, this peculiarity in morphology is not present, the bacilli in such cases being undistinguishable from those of human sputum. I have not as yet had the opportunity of examining a sufficient number of specimens of bovine tubercle to venture an opinion as to the conditions on which this peculiarity in morphology, the short so-called bovine type, depends, but preserved specimens in my collection—cover-glass preparations—from other animals which have been infected with both the human and bovine bacilli, illustrate the following facts:

In the pig and sheep which have died from inoculation with bovine tubercle bacilli, the short form is not preserved. Smear preparations from the incised lung in both these species, the disease being generalized, show tubercle bacilli in great abundance and of the usual sputum conformation. In the pig, where I have also under certain conditions (a pre-existent swine plague pneumonia, or crude sputum inoculations) obtained a fatal generalized tuberculosis by inoculation with the human germ, the morphology of the bacilli is similar to that of bovine tuberculosis in the same animal.

In the rabbit and guinea-pig inoculated with bovine cultures exhibiting the short form, the results have been variable. I have slides in my collection in which the short type of bacilli can be recognized in smear preparations from these animals, while in others longer and medium forms predominate.

As to the form which sputum tubercle bacilli assume when grown in the organism of cattle I have unfortunately made no observations. In sheep and pigs the usual sputum form is maintained. In cattle the lesions resulting from such inoculations have been so slight and their contained bacilli so rare that no exact comparison is possible from any preparations in my possession.

In artificial cultures the bovine germ maintains the short type with more constancy. This has been especially observed by Smith in growing the bacilli on pasteurized dog serum. On the medium which I have usually employed—glycerinized beef serum—although the short form usually predominates, the distinction between these and cultures from the human is not always appreciable. Bovine cultures are more difficult to start and generally make a feebler growth than human. The naked-eye appearances depend chiefly, I think, on the scantiness or luxuriance of the culture. On Löffler's medium I have noticed that the human germ assumes the short form of the bovine.

An explanation of the conditions on which this variability depends is not possible with our present knowledge. It is manifest, however, that the source of the bacilli in the sputum of the human consumptive—human or bovine—is not to be determined by their morphology.

In comparing the animal tuberculosis with that of man, we have limited our discussion to the bovine disease. Tuberculosis, however, occurs in other mammalian species. It is not rare in pigs and is occasionally found in horses, dogs and cats, while a very few instances are on record of its occurrence in sheep and goats. Wild animals in the state of nature are, I believe, entirely exempt, but under confinement in cages some species are peculiarly liable to fall victims to this disease. Are we justified, in view of these facts, in assuming the existence of races of tubercle bacilli peculiar to each zoölogic species in which tuberculosis naturally

occurs? The very rarity of the disease in most of these species precludes this idea.

In pigs the source of infection can be traced to ingestion of the milk of tuberculous cows. Cats and dogs are infected in the same manner, or from close association with their consumptive owners. Although under conditions of close confinement, as in menageries, we may well believe that transference of the disease may occur between animals of the same species, the original source of infection is probably in all cases extraneous—either from mankind or from cattle.

In the case of the human and the bovine disease the conditions are different. In both these species tuberculosis is an extremely common affection. Contagion in cattle tuberculosis can frequently be traced without difficulty, and its source is in other cattle similarly diseased. We have seen from the experiments just described that a human origin of the cattle disease is hardly conceivable. If it occurs at all it must be under most exceptionally rare conditions. On the other hand, we may assert, I think without begging the question, that in most cases at least human tubercular disease has its origin so far as contagion is concerned in other similarly diseased human beings. We have here, then, the conditions on which depend the evolution of stable racial characteristics in the bacteria; namely, long-continued invariability of environment. We find, therefore, in these facts a theoretic justification in assuming, at least hypothetically, the existence of two races of mammalian tubercle bacilli, the human and the bovine. Practically this assumption is supported by the facts in reference to differences of morphology and pathogenic virulence just discussed.

DEDUCTIONS.

From the foregoing data we have now presented to us the task of deciding whether the experimental evidence tends to support or to refute the view that human consumption may at times have its origin by contagion from cattle. I can best introduce my own views on this matter by a quotation from my first report on tuberculosis, already referred to: "It can not be said that the facts here presented remove the question in any degree out of the domain of speculation. They really furnish more food for theorizing, and may either diminish or increase our suspicion of dairy products according to the process of reasoning employed. It may be argued, for instance, since bovine tubercle bacilli have been shown to be equally as virulent as those of human origin for all animals tested, and more virulent for some, the presumption is that they are more virulent for mankind also. Contrarywise it may be said that human tubercle bacilli being shown to be less adapted for growth in cattle than the bacilli of bovine origin, there is reason for believing that the converse may also be true." "If the bovine bacillus be regarded as merely a more highly virulent modification of the human variety, this should be shown by the greater gravity of the lesions produced by comparative inoculation experiments on all species of susceptible animals. If, however, there is a selective feature shown by such inoculations, the excess of virulence of the bovine variety being manifested only toward certain species of animals, some support would be gained for the theory of a distinction of races other than that founded on a mere difference in degree of pathogenic activity."

The tests necessary to determine this latter point have since then been made and the records are contained in my second report¹⁴ on tuberculosis (1900).

The bovine tubercle bacillus has been shown by these

experiments to possess an indiscriminate and not a selective excess of virulence over the human specimen. Similar results have been obtained by Pearson and Ravenel of Pennsylvania and by Koch and Schütz of Berlin.

In a purely speculative question it is a matter of everyday experience that the same data may lead to entirely different deductions. Professor Koch, whose attainments and achievements in bacteriology we all respect, has deduced the inference, largely, as we infer, from his experimental work on animals, that bovine tuberculosis can constitute no factor in the initiation of tuberculosis of man. Few of us, I think, will be able to follow this process of reasoning. Whether or not his view is correct it can hardly be said that it derives any support from the purely experimental evidence. I think there is a wide field for investigation yet to be covered before we as sanitarians can feel justified in recommending the discontinuance of those safeguards against infection from tuberculous dairy products which an unwilling public are just beginning to appreciate.

DISCUSSION*

ON PAPERS OF DRs. KNOFF, APPEL, CARRINGTON, BONNEY, STUBBERT, SALMON AND DINWIDDIE.

DR. M. P. RAVENEL, Philadelphia—We can hardly speak of this question without bringing in Koch. As you are aware, he laid down two propositions: First, that human tuberculosis differs from bovine and can not be transmitted to cattle; and second, that if man is susceptible to infection from cattle at all it is so rare an occurrence as to make precautions unnecessary. Now the first of these propositions is capable of being subjected to experimental proof. You will remember that Koch, in the experiments conducted by Shütz and himself, did not succeed in producing bovine tuberculosis with the human bacillus. In my opinion the conclusions of Koch were based on an insufficient number of experiments. At the laboratory of the State Live Stock Sanitary Board of Pennsylvania, we have succeeded in doing what he failed to do, and I have placed in the Scientific Exhibit specimens of animals that were infected with the human disease. One shows the liver and diaphragm to be affected. This was the result of an attempt we made at obtaining immunization; we got a result we did not wish for, but one that is of importance in establishing the fact that human tuberculosis can be communicated to animals. We must acknowledge that bovine animals, as a rule, show a high degree of resistance to infection from man.

Generally speaking, the pathogenic power of the bovine tubercle bacillus is considerably greater than the human for all experimental animals. Of course, this does not prove that bovine tuberculosis can be transmitted to man, but this can be proved without any trouble. We can not, it is true, carry out experimental tests as we do on animals, but there is a large

* The papers of this Symposium on Tuberculosis which have already appeared will be found in the following issues: Dr. Knopf, November 22 and 29; Dr. Appel, November 29; Drs. Carrington, Bonney and Stubbert, December 6.

The Symposium will be completed later by the following paper and its discussion:

Sanitary Measures for the Prevention of Tuberculosis in New York City, and Their Results. Herman M. Biggs, M.D., New York City.

the hands and extending to the forearms were several papules interspersed with scaly patches. The disease appeared for the first time March 16, and had accordingly existed only one month. The patient did not recall any previous eruption. The general health was good and no systemic cause could be assigned. The disease disappeared on the approach of warm weather a few weeks later. As the family moved away from Cleveland nothing further has been heard of the case.

CASE 18.—L. J., female, aged 32, seen April 29, 1895, presented a thick, fissured patch on the back of the left hand, which was well defined, slightly exudative and covered with thick crusts. The patient is right-handed. The margin of the lesion was slightly elevated and stood out in bold relief. There was a dark red or purplish tint especially noticeable when the hands were dependent or cold. The history of the disease as given by the patient is as follows: Nine years ago, during the winter, the eruption first appeared on the left hand. It disappeared at the approach of warm weather, and reappeared each successive winter, its advent, as nearly as the patient can remember, being co-existent with that of frost. Within a year or two of the first invasion the right hand became affected in like manner. Of later years this lesion has disappeared completely, while the patch originally invaded

Fig. 1—Dermatitis hiemalis, acute attack, the disease having existed for several years

on the left hand has continued to return in the same site each winter.

CASE 19.—L. D., female, age 16, first presented herself April 14, 1895. The patient was employed in a candy factory and handled colored powders. The eruption was situated on the back of the hands and on the fingers. The family history shows nothing of importance bearing on the disease. She gave the following history of the eruption: From the age of one to six years she had eczema, with pus oozing from fissures about the joints and on different parts of the body. After the age of six there was no disturbance of the skin until 1895, when at the approach of cold weather in January the present disease appeared. There was first noticed a roughness about the mouth, the skin became dry and was easily irritated, and this soon appeared on the dorsal surface of the middle finger of the left hand (the patient was right-handed). From this region it spread by the formation of similar roundish spots, quarter dollar in size, which gradually enlarged at the periphery until they attained the size of a silver half dollar. They were dark red in color, at times very itchy, worse at night, and especially when in bed. There were, at the time of examination, six spots on the back of the left hand. The palms were free. About two months ago it also came on the dorsal surface of

the right hand. These were smaller, being dime sized and six in number. The skin of the neck is also rough and slightly red, similar to that about the mouth. The patient has never had chilblains nor does she habitually complain of cold hands or feet. In making a diagnosis the following note was appended: "Dermatitis hiemalis, occurring in a skin predisposed to eczema. Just how much influence her occupation has on its causation is difficult to say. The present attack appeared during unusually cold weather."

CASE 20.—J. H. A., male, aged 3, seen Nov. 7, 1895. Sought relief for a disease of the skin of eighteen months' duration. It appears only on the exposed parts of the body, is of red color and feels rough. It was first noticed during cold weather, and the mother has noticed that it is always aggravated by cold. During the summer months it almost completely dis

Fig. 2—Dermatitis hiemalis occurring on the hands and legs, very rare occurrence

appears. The patient was under treatment during the whole winter. My next note was on Feb 15, 1898, the area involved being somewhat rough and inclined to fissure.

CASE 21.—G. E. C., male, aged 42, presented himself May 5, 1896. Patient complained of well-defined lesions which occurred on the back of the hands every winter and disappeared during the warm weather of summer. They always returned in the same positions, always occupying the same sites. There was nothing in the case calling for special description.

CASE 22.—L. P., female, aged 34, seen March 27, 1896. The disease came first in February, 1892, and has since returned each March and has always disappeared early the following summer. This year it appeared during the cold weather which occurred during the first part of the month. It is limited to

the back of the hands, and occurs in circumscribed spots. It has extended up the forearms to a slight extent. A piece of skin was removed for microscopic study. As a child the patient was troubled with chilblains and had eczema of the face. My notes show that on April 3 the hands were better. This date followed a spell of warm weather which had prevailed for a week or more. Then there came a heavy snow storm with northwest winds, and the patient immediately became worse with chills and cutis anserina.

CASE 23.—W. T., aged 35, was seen April 17, 1899. The disease first appeared four years ago, in the form, according to the patient's statement, of a "dry blister," or a "small vesicle," not itchy, and later accompanied by "small blisters leaving crusts" in patches about the size of a dime. The following winter it broke out again and was very itchy, accompanied with much watery exudation. It has, the patient says, returned every winter since, and usually leaves during the summer. If present at all during the warm weather, it is only to a slight extent, and is then attributable to some slight irritation. On the back of the left hand (the patient being right-handed), there were two or three lesions about the size of a silver dollar. They were irregular in outline with prominent margins; some were fissured and dry, while the majority were moist, and in all slight itching was complained of. They had never appeared on the right hand nor on any other part of the body. During the spring of 1901 the patient returned for treatment; the hands were in a very bad condition, although not changed in character. The patient says last spring they gave but little trouble.

CASE 24.—E. H. P., female, aged 40. Under date of April 26, 1899, occurs the following note: "Disease occurred on the back of hands. First came in February of this year on the back of one hand. The lesion gradually extended and new spots are now appearing on the opposite hand. Patient complains of burning and itching. It looks like ringworm, has a prominent margin with a dry, scaly central area. General health good."

CASE 25.—J. E. T., male, age 26, dry-goods clerk, sought advice Nov. 1, 1900. He gave the following history: The disease first appeared three years ago, coming at the first approach of cold weather. The right hand was the most seriously affected, consisting of circumscribed patches, appearing in size from a dime to a half dollar. They were very itchy and always disappeared in summer.

CASE 26.—C. M., female, aged 25, servant, first seen Oct. 29, 1901. She presented a typical picture of the affection herein described (Fig. 1). The patient came to Cleveland from Ireland five years ago. In January of the following winter the present disease began. It appeared on the back of both hands. It remained during the winter and at the approach of warm weather became better, although the patient noticed a slight irritation on the back of the hands during the summer, so much so that she did not think she was entirely free from the eruption. The following winter it became aggravated, and during the present year it has appeared again with unwonted severity. There were, at the time of her first visit, reddish ringed lesions which tended to heal in the center while the margin was elevated and presented a more active inflammation. The patient complained of burning and itching. The left hand was worse than the right (the patient is right-handed). On the left hand there were two lesions, the size of a twenty-five-cent piece, of a brick-dust color, somewhat ring-shaped, which looked like ringworm. The eruption was moist, especially after rubbing. In the center some lesions were slightly scaly. Bits of skin were excised for histologic examination.

REPORTS OF MICROSCOPIC EXAMINATIONS OF SKIN.

The following histologic report of Cases 21 and 22 has been kindly furnished me by Dr. Thos. E. Ely of New York:

CASE 21.—The first specimen consists of several small fragments which show on microscopic examination the following changes:

1. In places where the lesion appears to be slight the only notable change is in an accumulation of small spheroidal and

epithelial cells in the corium about the blood vessels. This change is most pronounced just below the papillary layer in the earliest stages, but soon apparently affects the vessels of the papillæ also. When the papillary layer is affected there is also evidence of edematous infiltration of the tissues surrounding the affected blood vessels, both those of the papillæ and of the deeper portions of the corium, this change being most marked, however, in the papillæ, as a rule. These are the only changes observed in some of the specimens.

2. In others, however, further changes are apparent. In these the changes noted above are present, usually in considerable intensity, the edema sometimes being very marked, but in addition there are changes in the epidermis. Of these the most marked, and probably the initial change, is in the horny layer, and consists of swelling of the cells just external to the lamina granulosa, as if these cells had become infiltrated with a liquid. In consequence of this swelling the horny layer is

Fig. 3.—Typical case of dermatitis hiemalis, second yearly attack at first merely thickened, but even in apparently early stages of this infiltration a tendency to the formation of vesicles is shown by the occurrence here and there of a few small spaces of spheroidal shape and filled with granular material representing serum albumin precipitated in the course of fixation of the specimens.

3. In this stage also there begins to be noticeable a change which later becomes very pronounced, viz., a separation of the cells of the rete Malpighi, so that distinct intercommunicating channels appear between the adjacent cells. This change is seen first in the middle region of the rete where prickly cells are abundant, but extends from there in the more severe cases to the entire thickness of the rete. These channels are believed to have resulted from dilatation of the intercellular spaces. At times they have a width equal to about one-fifth the diameter of the epithelial cells adjacent to them, which under these circumstances seem to have undergone a change in the direction of their long axis. It will be remembered that in the normal skin the cells of the rete become 1 1/2

flattened and consequently elongated in the plane of the skin as they approach the surface. This natural change is observed to be less marked or wholly absent in those parts of the specimens where the intercellular spaces are considerably dilated, and occasionally the cells present their longer diameter even perpendicular to the surface of the skin. The intercellular spaces are for the most part devoid of cellular contents, but even in places where the dilatation is not greatest there are not infrequently a few infiltrating small spheroidal cells to be seen in them. These cells when isolated are for the most part mononuclear, have a small cell body, are very irregular in shape and stain deeply, from which characters they are believed to be mononuclear leucocytes wandering from the deeper layers to the surface.

4. In addition to the change in shape of the cells of the rete above referred to, it is also noticed that the bodies of many of them appear distinctly more granular than normal, and that even in the deeper layers small vacuoles have formed circumferentially about the nuclei. In those places where the changes are all more marked these vacuoles are seen to be much larger, occupying as much as a quarter or half the cell body. They appear in the specimens to be empty, but probably during life had a liquid contents. Occasionally the cell

Fig 4—Dermatitis hiemalis, the typical eruption, showing the herpetiform character of some of the lesions. They are usually encountered early in the course of the disease.

appears swollen and its entire contents appear to have given place to one large vacuole.

The changes above detailed represent the fundamental pathologic processes which have been observed, but they are combined in different proportions in different parts of the specimens. They have been presented, so far as possible, in the order in which they are believed to have occurred, and if this be correct, represent the various stages of the process. In those places where the accumulation of liquid is considerable, where the degeneration of the epithelial cells is marked and where their separation is wide, distinct vesicles are formed, often covered by a considerable layer of the epidermis. In some instances the contents of these vesicles seem to have been chiefly liquid, but in not a few occasional leucocytes, now polynuclear for the most part, are visible. The vesicles are formed in some instances in the horny layer and again in the more superficial layers of the rete, so that they can not be said to have any definite localization. In a few places the vesicles appear to have broken, discharging their contents and becoming covered by a crust of dried material.

Summary.—The changes observed in these specimens are those of an inflammatory process characterized chiefly by infiltration of the skin by a liquid exudate. In addition, how-

ever, there is moderate emigration of leucocytes and some growth of connective tissue cells (epithelial cells) about the blood vessels of the corium. As a part of the inflammatory process also there is degeneration and vacuolation of the epithelial cells of the epidermis, this combining with the liquid infiltration to bring about the formation of vesicles.

CASE 22.—The second specimen is a larger piece of skin, with some of the subcutaneous fat, etc., attached. The changes observed in it are in all essentials the same as those described as present in the specimens from the first case, although some of them are more marked in this specimen while others are less.

1. The same accumulation of cells about the blood vessels of the corium, both of the papillary portion and of the deeper parts, is observable. The edematous condition noted in the first specimens is also present, though less marked in this instance.

2. The swelling of the epithelial cells of the horny layer of the epidermis is exceedingly great in this second specimen, and there are frequent large vesicles here. The contents of these vesicles appear to have been serum for the most part, though a few polynuclear leucocytes are also present in most of

Fig 5—Dermatitis hiemalis, showing the appearance of the lesions after many years' duration, thickening of the derma well marked, itching severe.

them, not enough, however, to indicate the presence of "pus." In this specimen it would seem that there had been little if any excoiation of the superficial epithelium, and this suggests that it represents an early stage of the disease.

3. The separation of the cells of the rete Malpighi described in connection with the first specimen is here much less prominent, though discernible in many places. Here, also, an occasional leucocyte may be seen in the dilated channels.

4. The granular and hydropic degeneration of the cells of the rete are also less prominent in this case.

Summary.—It will be evident, then, that there is much similarity in the changes observed in the two cases, but that in the second the swelling of the horny layer is the most pronounced feature, while the edema of the corium and of the rete Malpighi is here less marked. The conclusions adduced from the study of the first case consequently apply to this second case also. The impression gained from the study of the second case is that it represents an earlier stage of the disease.

During the past winter Dr. Edwin Perkins Carter has studied bits of skin taken from Cases 22 and 27. In both instances the character of the skin lesion was typical of the so-called eczema hiemalis as described above; and the histologic examination was made with

a view to determining what, if any, peculiar or characteristic pathologic changes were present. Dr. Carter reports as follows:

CASE 22.—The tissue was secured about the sixth day after the first appearance of any skin lesion, and the changes present were as follows:

The stratum corneum shows everywhere the evidence of excessive exudation, while three large vesicles stand out prominently with but an extremely thin epidermal covering. Under high power the free masses of red blood corpuscles caught on the surface and in the edematous meshes of this layer, testify to the occurrence of real, and to a certain extent of accidental hemorrhage. Here and there a few scattered leucocytes are to be seen. These vesicles are filled with a clear serum and des-

Fig 6—Dermatitis hiemalis, first attack, showing more acute form of inflammation with vesicles, and the distinct elevated margin described in the text.

quamated cells, and contain almost no polymorphonuclear leucocytes. Where they have formed the upper layers of the rete Malpighi have given place to them, with the usual resulting thinning of the rete in these areas. Elsewhere the rete Malpighi shows some slight increase in thickness, and in several areas, as one approaches the corium, there is quite marked evidence of a mild inflammatory reaction, as illustrated by the infiltration of polymorphonuclear leucocytes and the amount of edema present. In many cases the cells in the stratum granulosum are swollen and edematous, taking the stain but poorly, while in others again they remain unaltered. In the reticular layer of the corium, in addition to some slight vascular dilatation, there are here and there scattered foci of polymorphonuclear leucocytic infiltration and edema. No where is there any small round cell infiltration.

CASE 27.—In this case the tissue was secured at an even earlier stage of the disease, and the changes present are of so slight a character as to hardly merit a description. The upper layer of the derma showed no alteration, and the only evidence of any pathologic change was to be found in the slight vascular dilatation present, and in the edema of the upper layers of the rete Malpighi.

¹ Summary.—From the observations made on these two cases there is no evidence that the process differs in any way his-

tologically from an ordinary eczema. The stage of the changes depending, as in any case, on the length of time during which the process has been active, together with the susceptibility of the individual skin affected.

THE AUTHOR'S CONCLUSIONS.

From a careful clinical study I am convinced that the affection is more closely allied to the erythemata than was at first supposed. Not only is the color suggestive of some forms of erythema, being of a dark bluish tint, but like erythema, it more frequently attacks the distal extremities or parts farthest removed from the center of circulation. Again, like the erythematous group, it is more frequently met in the months in which there is the greatest variability in temperature, which prevails most frequently during the early winter and the early spring months. The histologic findings made by Dr. Ely and by Dr. Carter show nothing distinctive, and the extent of changes in the skin seems to be wholly dependent on the amount of circulatory disturbance. That cold may be regarded as a causative factor in the affection seems to me to be well established; that the same influences are causative in the erythematous group is likewise generally accepted. I would therefore regard the disease as one allied to eczema, while characterized by

Fig 7—Dermatitis hiemalis of many years' duration, inflammation less active, hypertrophy beginning to take place

some of the clinical features of erythema, presenting a clinical picture quite distinct, which further observation may show is entitled to be looked on as a disease *sui generis*.

Should a distinct name be called for, the most appropriate, it seems to the writer, is the one proposed, dermatitis hiemalis.

TREATMENT.

Little can be said in regard to the treatment of the affection. Thus far the internal administration of ichthyol, as reported in one of my previous communications, apparently was of benefit in one case—the disease having disappeared under its use without the assistance of warm weather. The most benefit, however, has been derived from local measures. The application to be selected naturally depends on the extent of the inflammation, and whether or not we have an excoriated area or a thick and hypertrophied condition of the skin to contend with. In the former condition some slightly astringent, soothing application, such as the glycerid of tannin, diluted with distilled hamamelis (1 to 3), lead wash, or the evaporating lotion of Hutchinson (liquor

plumbi 5ii, spts. rectificati 5iii to aquæ q. s. 5viii). When the disease has become chronic with hypertrophy, salicylic acid grs. xx, ung. diachyli 5ii. In place of the diachylon ointment, mercury or tar may be used in ointment form. In all cases the hands should be protected by wearing leather gloves, and when practicable a change of climate affords the most certain means of immediate relief, although it does not eradicate the tendency to the disease.

DISCUSSION.

DR. W. S. GOTTHEIL, New York—The cases described belong to a class not unknown in the east, though we are accustomed to give them a different name, and do not recognize the relationship to erythema that the essayist ascribes to them. Precisely similar cases in our clinics are called mycotic eczemas; they are recognized as eczematous, and are called mycotic on account of their peculiar margins, course, etc. That they get worse in late autumn and early spring has also been noted.

DR. M. L. HEIDINGSFELD, Cincinnati—I have long been impressed with the frequency with which these cases occur, and with the large rôle they play in dermatologic practice in Cincinnati. I am also impressed with what Dr. Gottheil remarks on, and the clinical manifestations have lead me also to believe that there is some parasitic nature to this affection, though histologic and bacteriologic proof is still lacking. The same predisposing influences which Dr. Corlett mentions exist in Cincinnati. Personally speaking, these cases, in previous years, have proved to be very obstinate and rebellious to therapeutic measures, and during the past year I have found the x-rays to be a very valuable and efficient measure for their treatment. As far as my personal experience permits me to state, I believe that the results from the x-ray are not only prompt, convenient and effective in the treatment of this affection, but also permanent.

DR. M. B. HARTZELL, Philadelphia—I think we have all seen cases of this kind, and it seems to me that what they should be called depends largely on their etiology. I am sure I have seen cases like these which have resulted from external irritants. In some instances the irritant was discoverable, but in most it was unknown. If I understood the writer of the paper correctly, the histology differed from that of eczema. As to whether we shall call this affection dermatitis hiemalis or eczema will depend somewhat on our definitions of dermatitis and eczema. I would deprecate qualifying the disease as mycotic. That seems utterly without reason. No one has ever discovered a micro-organism in these cases, and the presence of a sharp margin is not a sufficient reason for calling them mycotic.

DR. F. H. MONTGOMERY, Chicago—Dr. Corlett has given a very clear demonstration of a fairly distinct local type of a larger class of disorders to which Dr. Hyde called attention some fifteen years ago. By comparing, month by month during a period of three years, the number of cases treated with the temperature chart of the weather bureau, he demonstrated that these conditions were exaggerated and largely due, not so much to cold as to sudden temperature changes; a sudden change from cold to warm weather being effective, though less so than an equally sudden change in the opposite direction. I would like to ask Dr. Corlett whether he has recognized this influence of a sudden change in temperature on the cases which he has described to us.

DR. CORLETT—I am loath even to attempt to add to the already long list of skin diseases, but I have a fixed impression that the cases herein detailed represent a distinct clinical entity, while from a pathologic standpoint no distinct picture may be drawn. As I have said, my observations are based on clinical experience.

In regard to Dr. Montgomery's question, in my paper read in London I gave a table of the climatal changes occurring on the south shore of Lake Erie for a certain period of time, and in that table I called attention to the fact that these dermatoses were apparently dependent on a rapid change in temperature, but that my observations were always on the same altitude.

CONCERNING MORPHIN ADDICTION AND ITS TREATMENT.*

C. B. BURR, M.D.

Medical Director, Oak Grove Hospital for Mental and Nervous Diseases.

FLINT, MICH.

Of the last twenty cases of morphin addiction which have come under my observation, eight were physicians, one was the wife of a physician and one the daughter of a physician. Fifty per cent., therefore, occurred among physicians and their families. It is difficult to account for this appalling fact. I have fallen to wondering how much the disposition to test and try had to do with this and how far failure on the part of teachers to emphasize to students the dangers of the morphin habit was responsible for it. In some instances I am regretfully forced to the conclusion that the taking of the narcotic was from pure self-indulgence. In one case in particular, that of a young man who acquired the habit in student days, there was no attempt at self-extenuation or excuses. He did not even justify its first use on the ground of experimentation as to its effects, but admitted dallying with it and forming the habit as one might that of tobacco. His mental organization was cast in the dreamy mold, and I am not at all sure but that previous indulgence in cigarettes to excess had much to do with the subsequent resort to the, to him, more delightful stimulation. In the majority of the eight cases, however, I think it unquestionable that the habit had been acquired because of demand on the part of the system for temporary lifting up after exacting professional duties. No doubt in most of such cases the physician to secure repose and rest from the boneache and nerverack has taken a small hypodermic with a feeling of perfect indifference as to danger. He has been perfectly well aware of the insidiousness of the drug and the danger of the formation of the habit, but has, because of this very assurance, felt there was no likelihood of its obtaining the mastery. It would seem, however, in the light of these facts, that a grave responsibility rests on teachers of therapeutics to instill into the minds of students a wholesome fear of this blasting and deadly narcotic. It is my belief, based on the experience of a good many years, during which I have had many painful neuralgic conditions to treat, that it is used far more than there is any need. It is too frequently the first resort. The physician is apt to follow one dose with another, and another, and when he finds to his distress that his patient is clamorous for the drug and will not hear of its suspension, he realizes, perhaps for the first time, the perils of the situation.

Paradoxical as it may appear, some of the most difficult cases to treat have been those of short duration, and the least difficult those displaying a complication of habits, as liquor and morphin, or cocain and morphin. The latter have frequently borne the abrupt withdrawal or the rapid reduction of the drug with less constitutional disturbance than cases of the morphin habit pure and simple. I have never known a case attended with greater discomfort than that of a young man under twenty-five who had used morphin but three years, and who was taking, as far as could be learned, not more than three or four grains per diem. In this case the nausea and vomiting, cardiac disturbance, pain and nervous manifestations were extreme, and would have been alarming except for the age and strength of the

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Richard Dewey and H. A. Tomlinson.

patient. Circumstances were such that the abrupt withdrawal of the drug was imperatively necessary. Whether the symptoms would have been materially modified had some other method of treatment been resorted to, I am in doubt.

On the other hand, the case which presented fewest difficulties in the way of treatment was that of a physician, aged forty-eight, who had used liquor and morphin for thirty years, beginning the employment of morphin for sick headache. Both had been taken in great excess for seven years. He had had one attack of delirium tremens, followed by mental disturbance, which continued for two months. He once reformed under the gold cure, but relapsed. Within the twenty-four hours previous to his admission to Oak Grove he had consumed three pints of whiskey. He took regularly every two hours or thereabouts in the twenty-four hours the following drugs in pill form: Acetanilid, 3 gr.; citrate of caffein, 2 gr.; bicarbonate of soda, 1 gr.; morphin, 3-8 gr.; nitroglycerin, 1-100 gr.; tincture digitalis, 2 drops; tincture strophanthus, 2 drops; strychnin 1-30 gr.

Immediately after admission to Oak Grove he was given a Russian bath and his clothing and effects were carefully examined, a few tablets of morphin being removed. During the evening he complained of acidity of the stomach, which was relieved by the administration of aromatic spirits of ammonium, quinin and sodium bicarbonate. Compound syrup of hypophosphites was prescribed, t. i. d. At bedtime 15 grs. of sulphonal were administered. He passed a comfortable night, sleeping well, remained in bed all the day following admission, dropping asleep before dinner time and sleeping soundly until midafternoon. On waking, the heart's action was sixty-four, but soon rose to seventy-two. He was depressed in spirits, but showed no physical perturbation. Two days later he sat up. It was noted that he felt comfortable. "He complains of no unpleasant symptoms except slight headache and weakness." Three days later the note is made that "his appetite is very much improved and he is gaining in strength. He walks about the grounds and goes driving," and one week later that, "he continues to gain in strength and mental operations are clearer." It is a singular fact also that there is an entry to the effect that constipation has been overcome by the use of cascara and glycerin suppositories. As all will agree, constipation as a symptom following the withdrawal of morphin is most unusual. He was removed from Oak Grove two months following admission.

The experience in this case and in a similar case where the patient had been taking morphin, whiskey and cocain (the withdrawal of all three of which was productive of no constitutional disturbance) would seem to indicate that as a preparation for a course of treatment looking to the withdrawal of morphin, it might be well to prescribe for a period of weeks or months a small allowance of whiskey and cardiac tonics, such as digitalis and strychnin.

As a rule, patients who place themselves voluntarily in the care of a hospital for relief from a drug habit, are deeply imbued with the necessity for this and are desirous, for financial or other reasons, that the habit should be corrected at the earliest possible moment. In such cases where physical strength will permit and one has the full co-operation of the patient and can watch the case for untoward symptoms, it is frequently expedient to discontinue absolutely and at once, opium and all its preparations, substituting strychnin, quinin, kola, coca, champagne, aromatic spirits of ammonium,

according to circumstances and giving hypnotics at night as indicated. In prescribing chloral in such cases, it is well to combine it with quinin or strychnin, and I find that at the height of constitutional disturbance and physical distress the third day after the withdrawal of morphin, a hypodermic of a quarter to a half a grain rests the system, brings about relief from nervous tension and does not interfere with the progress of the case; in other words, treatment may go on as before after the use of the hypodermic.

An interesting case came under observation not long ago, in which the patient had been using the following drugs: Sulphate of strychnia, 1-60 gr. every 4 hours: for a stomach and bowel difficulty, salol and charcoal of each 1½ gr., subnitrate of bismuth, 6 grs., extract of nux vomica, ¼ gr.: for inaction of the kidneys acetate of potash, 12 grs., spirits of nitrous ether, 10 minims, every hour until four doses had been given; of morphin, 26 grs. in 24 hours in divided doses; of paraldehyd, a small teaspoonful every hour. She was also requiring the use of a spray and mouth wash in consequence of salivation from paraldehyd.

In this case paraldehyd was discontinued immediately, the other prescriptions given at longer intervals until discontinued and the morphin rapidly reduced. It was practicable after three weeks to discontinue the use of morphin altogether.

Much has been said and written about the greater fortitude of women than men in bearing suffering, and my experience with morphin habitués bears this out. The most heroic patient I have ever known was a woman who had been taking in the neighborhood of fifteen grains of morphin daily for a number of years. She insisted upon having the drug immediately and totally withdrawn and her wish was complied with. I am satisfied that her sufferings were acute, but she bore them with a stoicism and a restraint of the emotions deserving of all praise. Hardly a groan escaped her. She set her lips and teeth and never gave way to lamentation or outcry. I have often thought that for cool, clear grit this case shone out with unparalleled brilliancy. Her sufferings were over in a week and she recovered rapidly, as she deserved to.

Two cases came to Oak Grove of one of whom it was alleged that there had been used large quantities of liquor and cocain and of the other, cocain and morphin. In the latter case the allegation was admitted as to the past, but it was declared by the patient that he had recently discontinued both. In the former case the use of whiskey was admitted, but that of cocain denied. In neither was anything of a spirituous or narcotic character prescribed after admission and the practical absence of constitutional symptoms seemed to bear out in a measure the contention of the patient. I had a suspicion, however, in at least one of the cases, that extreme strength of will and the determination of the patient to maintain his position against that of those who had been instrumental in placing him under treatment buoyed him up and operated as a strong auto-suggestion to modify the symptoms of constitutional disturbance.

One case was that of a woman of advanced age, 73 years, and was complicated by feeble heart. Notwithstanding the latter condition, rapid reduction of morphin was resorted to and in the end complete recovery occurred, although at one time there were alarming cardiac symptoms. Experience in this case confirms me in the belief that the dangers from abrupt or rapid withdrawal of morphin are somewhat exaggerated. Personally, I have never known fatal results to follow the with-

drawal of morphin except in one case. The case was encountered many years ago while I was connected with the asylum at Pontiac. The patient was a young man in apparently vigorous health who had become so thoroughly disgusted with the slavery to appetite that he determined to be released from bondage at once. He was so fearful that morphin even in small amounts would be given him concealed in other medicines, that he absolutely refused to take medicine of any kind. Three or four days after the withdrawal of the drug, he got up from bed against the advice of the physician and insisted upon being shaved. He complained of feeling ill when in the barber's chair and returned to bed, where he was found a few minutes later, dead. There is no reason to doubt that had this patient taken suitable sustaining remedies and received the nursing attention which was desirable, he would have escaped the sudden heart failure which caused death.

As may be inferred from the foregoing, there is no plan of treatment that I permit to dominate me or tie my hands in any case. As a rule, I prefer the abrupt withdrawal or rapid reduction of the drug for various reasons, chief among which are that by dispensing with it as early as possible, the amount of suffering is limited, and that it is an injustice to the patient to stretch over a period of months something which may be accomplished in as many weeks. I would not, however, minimize the importance of keeping the patient under disciplinary control and observation as long as may be necessary, during which period the nervous system should be built up, and fortified against subsequent temptation, by the use of tonics, calisthenics, good food and diversion.

DISCUSSION.

DR. D. R. BROWER, Chicago—I congratulate the Doctor on his excellent paper and am sorry to have to add my testimony among our profession and their families. I have had a good many just such experiences as he has had. Of course, I know Dr. Burr well enough to know that his judgment is most excellent in his remedial measures and I agree with him that in properly discriminated cases the sudden withdrawal is the best method to pursue, but so far as my clientage is concerned I find very few cases in which I think this can be done. In my early experience with morphin habitués I had several cases of insanity following the rapid withdrawal of the drug. Since then I have been extremely cautious about it. I agree with Dr. Burr as to the rapid but not the immediate withdrawal of the drug. In more recent years I have never had a case in which I thought the immediate withdrawal could be done with any advantage, excepting in the case of a physician's wife, and even then I did not advise it. She did it on her own responsibility. From taking a very large quantity of morphin daily she came to the conclusion that she would stop at once, and stop she did, exhibiting that wonderful heroism already described. Of course, we kept her well sustained with strychnia and other tonics. My personal experience in recent years has been against the immediate withdrawal.

DR. H. A. TOMLINSON, St. Peter, Minn.—I am always reminded, when I listen to the discussion of this subject, of the controversies which accompany the discussion of the treatment of typhoid fever and pneumonia. Plans of treatment, apparently diametrically opposed, are vigorously advocated, and each seems to be successful. So it is with the treatment and management of the victim of the abuse of narcotics. I do not wish to be dogmatic, and am willing to admit that there is no fault to be found with the logic of those who advocate the gradual withdrawal of the drug, in cases of morphin or cocain habituation, but I am doubtful as to the soundness of their premises. It has always seemed to me that the difference was the same as that between poulticing and lancing a boil. Both methods will successfully evacuate the abscess, and the incision by the knife certainly hurts most at the time. Per-

sonally, I have never seen a case of drug habituation where I have not been able to stop the use of the drug immediately; and while there has been sometimes a great deal of depression, and even apparent collapse, yet the result showed that no harm had been done, and the more rapid recovery of the patient proved that the method was the best. It is true that I have always had my cases absolutely under my control; and I have relied largely on hydrotherapeutic measures and active and persistent feeding. I have withdrawn the drug immediately in a case where 60 grains of morphia, 60 grains of cocain and one quart of whisky were taken every 24 hours, without the slightest ill-effect; although there was acute mental suffering during the first 48 hours. While the patient complained bitterly at first, he afterward admitted that the course followed was the best. I have recently had under my care a physician who came to me an absolute wreck physically and insane. He had been taking morphia and alcohol certainly, and other narcotics probably, in increasing doses since 1892; and had frequently been the subject of so-called cures. He was told frankly what method would be pursued, and while he demurred at first, he submitted. This case was, in my experience, phenomenal, because the patient had very little discomfort, slept well after the first night without hypnotics, ate heartily, and within a week was as well as these cases usually are at the end of a month. I would like to call attention to a fact in my experience, in the treatment of these cases. Those people who take both alcohol and morphia seem to recover more rapidly than those who take morphia alone; and not only are the immediate results better, but the permanent recovery seems to be more certain. It is possible that there is some antagonism between these narcotics, or else that in taking both the victim takes less of either one. There is another fact in my experience which I have not heard referred to. In those who have been morphia, and particularly morphia and cocain habitués for more than a year, there seems to be a permanent loss of the capacity to tell the truth; a sort of moral reduction which remains after apparently complete recovery. He seems to become a gratuitous and usually a purposeless liar. I do not know what has been the experience of others in this respect, and it may be that it has been so in my experience because those cases coming under my care have, as a rule, also been insane, at least temporarily. I do not mean to affirm that there are no exceptions to this rule, but only that I have not met them.

DR. J. H. MCBRIDE, Los Angeles, Cal.—The problem of the morphin habitués is not more to stop his taking the drug than to keep him from returning to the use of it. There are certain aphorisms which it is well to observe in curing the patients of the habit. They should never know how much of the medicine the physician is giving them nor when a reduction is made, nor when the last dose is taken. They are morbid and suspicious and if they know what is being done are certain to criticise and make trouble. The morphin taker is a moral cripple because of the habit and I think it leaves a scar from which they rarely recover. The proper place to treat these people is in institutions and it would be better if they could be kept under surveillance for a year until the nervous system regained its normal tone. I have little faith in the permanency of the cure of the morphin habit. In the many years I have dealt with them I have had charge of a large number and I think I could count the permanent cures on my fingers, possibly on my thumbs. They go away apparently cured; but if they have care and hard work, this, with their weakened will power, leads them to return to the habit and so it comes about that their last state is worse than the first.

DR. JOSEPH COLLINS, New York City—I do not know that I quite understand what the reader of the paper means by the sudden withdrawal of morphin, but if he means the withdrawal of it on the day that he begins the treatment of the patient, as I presume he possibly does, I would state that my endeavors to do that have been singularly unfortunate. If he means by the sudden withdrawal of morphin what I mean when I say that the drug should be withdrawn within

the first week or ten days, then that is the plan to which I hold allegiance and the plan which, with few exceptions, I have never had reason to regret. It seems to me that in all the cases, except those in which the morphin habit has been acquired to overcome the asthmatic neurosis, that the drug can be stopped within the first ten days or first fortnight. Dr. Tomlinson says that he has never seen a case in which the drug could not be stopped suddenly. I must infer that he has never had a case in which the habit was acquired through morphin given to control asthma. It is certain that if a man gets a profound asthmatic paroxysm, you are going to give him some morphin at the time, or he is going to die; at least, that has been my experience. I have no difficulty in the treatment of any case of morphin addiction in cutting down the drug to one-half grain per diem, although the patient may have been taking from ten to one hundred and twenty grains per diem before coming under treatment. In some cases this results in suppression of the solid matter in the urine, associated with a condition of the colon, such as membranous colitis, in which, if some morphin is not given for a week or ten days following, the patients do not get well. The only factor in the treatment of the collapse, which occurs at the end of the first week or thereabouts, the time when the morphin is withdrawn completely, which is not spoken of sufficiently in the books and in articles treating of this subject, is the use of the very hot bath. I recall a case that was under treatment two years ago. The morphin had been withdrawn rapidly and the patient had passed into a condition of collapse. It appeared that death was imminent. He was put in a tub of water at a temperature of 120 F. for a few minutes, probably one or two minutes. The results were more striking than from any other stimulant that I have seen. A few repetitions were sufficient to tide him over the condition of collapse. I would be wretchedly unhappy if I believed for a moment that Dr. Tomlinson's conviction regarding the veracity of the cured morphin habitué was general. Morphin habitués, when they really recover, are just as capable of telling the truth as I am or as any other person made in the same model or cast in the image of God. I believe that this idea that the moral sense of morphin habitués is completely perturbed is an absurdity that has been handed down from generation to generation. Some of the best citizens in New York, some of the most brilliant minds in our profession, some of the masterpieces of evolution's handiwork, have recovered from the morphin habit, and they are just as good citizens and just as good pillars of society as those who have never taken morphin. I am very much interested to hear gentlemen connected with institutions talk about the morphin habit. I was particularly interested in reading Dr. Crothers' book, in which he says that patients should be treated in such institutions. But how are we to get them into institutions? You know, Mr. Chairman, and I know, that in our state we can not do any such thing. We can treat a morphin habitué when he comes to us, the same as we can treat a typhoid fever patient when he comes to us. We have no more right to deprive a man of his liberty because he takes morphin or takes cocaine than we have to shut him up because he chews tobacco. I agree with the reader of the paper and with Dr. Tomlinson that the institutions are the best places to treat these patients, but the first thing to do is to get your bird in a cage before you count his feathers. As far as keeping them in an institution is concerned, I think that is a splendid idea, if it could be enforced, which, unfortunately, it can not. We keep them in institutions—if we have been able to persuade them to go—just as long as they want to stay and no longer. That is the reason why we do not permanently cure more morphin patients. What we need at present is legislation empowering the keeping of such persons in institutions until they have recovered.

Dr. A. B. RICHARDSON, Washington, D. C.—I have listened with great pleasure to the Doctor's paper and wish to say that it corroborates my experience in almost every particular, especially in regard to the large number of these cases that we find among physicians and their families. In regard to the withdrawal of the drug, it seems to me that the indications that should guide us are the physical disturbance rather

than the psychic impression or the physical distress as described by the patient. I doubt whether gradual withdrawal of the drug very much diminishes the sum total of the patient's suffering. In the gradual withdrawal his sufferings are extended over the greater length of time throughout which it continues. We all know that as long as a patient is taking any of the drug at all, there will be a certain amount of psychic disturbance, which is not removed until the drug is totally displaced. There is one condition, or rather an interesting fact, in regard to the method of treatment that came to my knowledge a few days ago, and were I to mention the name of the author of this treatment, I am quite sure you would be surprised that a physician of the prominence of this man should advocate such a method of treatment. A physician of Washington called me in consultation to see his wife who had been a victim of the morphin habit for a good many years. I had been consulted in the matter a good many times. He told me that she had been seen by some of her relatives and that a physician in the neighborhood had stated that he had a new cure for the opium habit. She went under the care of this physician, and in two or three weeks the Doctor went over to see his wife and was told that she had entirely recovered; that she had been free from the use of the drug for two weeks, which had been suddenly withdrawn when the treatment began. The husband made inquiry as to the nature of the treatment and found that it was by means of hypodermic injections of hydrobromate of hyoscin. I do not know the size of the dose. In a very few days the patient was attacked with a violent attack of acute mania, and was sent to an institution where she still remains. When she entered the institution she was very much depressed, and in such a condition that the superintendent did not think there was any hope at all, but by careful nursing and careful attention to her heart finally the collapse was overcome and the patient is now gradually improving. It seems to me that in any treatment for the drug habit, we should not use anything that is so depressing as a treatment of this kind. I was very much surprised that this physician, who is an extensive writer on medical subjects, should have conceived this new cure for the drug habit.

Dr. W. J. HERDMAN, Ann Arbor, Mich.—I would not prolong this discussion, except for its extreme importance to us all. A matter of this kind always recalls to my mind the story of the old farmer and his sons who, after a freshet, were trying to rescue some of their sheep which had gotten out of the pasture into the stream, and the old farmer and his sons stood on the bank of the stream, and as each sheep floated down with the current, at great risk and great labor, they would rush in and get it out and bring it to the shore. Suddenly the idea struck them that they had better go further up the stream and discover how the sheep were getting into the stream. They did so and found that the sheep were in the corner of a field where the ground was being washed away and they could not help themselves from falling in. So they simply opened the fence and let the sheep out, thus doing away with the labor of catching them as they came down the stream. Now, Dr. Burr has said that 50 per cent. of all the cases of the drug habit that have come under his observation have been physicians or in physicians' families. That statement has been confirmed by several who have spoken on this subject. The fact of this drug habit is a sad thing and when we consider that such a large percentage of the persons who are thus addicted to the use of such a drug and who become victims of it are persons who are themselves in a position largely to discourage drug taking, then it becomes even sadder. If 50 per cent. of the victims are physicians, then 50 per cent. of those who become habitués are the results of the unwise and injudicious use of such a drug as this in the practice of physicians. As a teacher, I have noticed this disposition for years among the advanced medical students. I do not say that it is a very prevalent habit, but I do say that it is a very common habit among the students, especially when they are approaching examinations. In order to meet the demand on their energies, in order to meet the emergency, students in medicine are very likely to buoy themselves over that particular strain by means of a drug. It is sometimes strychnia,

it is sometimes morphia; at other times it is bromid, at other times it may be cocain, but they are very likely under such a strain to resort to some drug instead of to physiologic, healthful and normal methods of meeting the demand. Now, if a young man goes out into practice with this habit established, and is confronted with the emergency and the demands of the exigency of his practice, he is then much more likely to resort to such methods for himself. In addition I have noticed this tendency in young men going out into practice. They are brought into the presence of pain; naturally their whole desire is to relieve it. If the man who has preceded them has not made a very brilliant record; if it is a case of neuralgia, for instance, or a case of locomotor ataxia that has been somewhat aggravated, that young man desires to do something promptly, something spectacular, and he is very apt to take out of the locker the most powerful drugs that he knows anything about and employ them, forgetting the consequences of the thing, forgetting that he may be doing an injury to the patient that eventually will be a vast deal worse than the present pain, and I believe that this manner of dispensing on the part of these young men, and the teacher of these young men is very largely responsible for many of these conditions. In regard to the teachers of therapeutics, I think it is unfortunate that the teachers of this subject should not have more practice in dealing with patients. So large a percentage of the teachers of therapeutics are laboratory men at the present time, animal experimenters, men who can tell you what a drug will do to the circulation, what its effect will be on the respiration, and yet they have not had that experience in dealing with humanity that brings to their notice the influence of habits. The necessity of cautioning these young people with reference to the ultimate effects of using these drugs indiscriminately is very apparent. I think that the method of teaching at the present time is, to a certain extent, responsible for this result. So grave has this question appeared to me from time to time and the cases that have come to me, and the difficulty of properly handling those that are not in institutions and, as Dr. Collins has said, can not be brought into institutions, that I feel it must appeal to all of us. As Dr. Tomlinson has said, the dealing with these cases under such circumstances is very difficult, and I have not failed in my attempt to impress on the minds of my students how unwise is the indiscriminate use of these powerful drugs. I frequently say to them, "I am engaged in practicing neurology, and perhaps have more occasions to deal with pain and its manifestations than the average general practitioner. I do not make use of probably two grains of morphia in the course of a week on an average, and I am very seldom called into consultation with general practitioners who do not use anywhere from 10 to 15 to 40 to 100 grains of morphia per week. Now, gentlemen, if I, in the class of practice that I am engaged in, can get along with such a small amount of a dangerous drug, certainly it is not necessary to make use of it to the extent that is being done. I accomplish this partly from sedatives, partly from the use of other methods and it is far better, even for the immediate results, than the use of these powerful drugs." Now, the thing that ought to be impressed on our minds is that the preventive means are going to be the most productive of good results and are the ones that we should keep before us in our methods and to which we should direct the attention of our brother practitioners and those who are to take up this work in the future.

DR. BURR, in closing—My principal reason for reading this paper was the apparently growing tendency, as indicated by journal articles, to the treatment of drug addiction by the very, very gradual reduction of the drug; the reduction drawn out over a period of months. This treatment I have never yet found necessity for and my own experience with the disease would contra-indicate it. In reply to Dr. Collins' question, as to what I mean by the abrupt withdrawal of the drug, I mean the withdrawal absolutely of the drug within two or three days. The treatment which he recommends—the withdrawal of the drug within ten days or two weeks—I would call the rapid reduction of the drug. I agree with him that you can reduce the amount during the first two or three days to a very, very small percentage of what the patient has previ-

ously been taking. You can reduce the amount to half a grain or a grain, even where the patient was previously taking very much more. There is in Michigan a law which gives good results, and some patients have been placed under my care in consequence of it. The law permits the placing of a patient who is addicted to any drug habit under guardianship, and then by the consent of a judge of probate court the guardian may place his patient in an institution for treatment for the habit. This law is similar in its operation to those for the commitment of the insane.

I agree with Dr. McBride that it is very important not to take the patient into consultation in regard to matters of treatment. I am in the habit of saying to the patient the moment he comes in: "You must not ask me what I am giving you; you must not ask me how I am treating you; you must not ask me the amount of medicine you are taking, nor what you are taking, because I do not wish to be discourteous. If you do ask any questions I shall be compelled to say that I can not answer. So let us have that understanding in advance, that I can not tell you what you are taking." If I give a hypodermatic, or if I employ medicine in any other way, I am very particular that the patient shall not know the contents of the medicine or the contents of the tablet or the contents of the hypodermatic, whatever it may be. To sum up again, I favor, as a rule, the rapid reduction of the drug in the treatment of these cases.

CHOLERA ABOARD THE U. S. ARMY TRANSPORT SHERMAN.

EXPERIENCES OF THE ARMY SURGEONS IN CHARGE OF THE CHOLERA CASES, SUSPECTS AND CONTACTS DIS-EMBARKE IN JAPAN FOR QUARANTINE: DESCRIPTION OF THE NEW JAPANESE ANTI-TOXIN AND CHOLERA VACCINE.

WILLIAM C. MABRY AND HARRY C. GEMMILL.
CONTRACT SURGEONS, U. S. ARMY.

August 26, at 4:30 p. m., the U. S. Army transport *Sherman* left Manila, P. I., to enter on five days' quarantine at Mariveles Bay preparatory to sailing to San Francisco via Nagasaki, Japan. The *Sherman* arrived at Mariveles at 6 p. m.

During the ensuing night a first-class passenger became ill and on the 29th died of Asiatic cholera. The transport was at once disinfected and held an additional five days in quarantine, when, all danger having passed, September 4, she proceeded on her voyage.

September 7 another case of cholera was discovered, and up to the time of the *Sherman's* arrival at Nagasaki, 5:30 p. m., September 9, three more cholera cases had developed, and of the four soldiers thus affected two had died and been buried at sea.

The Japanese quarantine authorities came aboard at once on the ship entering the bay and removed the two surviving patients (one in a dying condition) to their quarantine hospital and held the transport for disinfection, a process which they subsequently administered most efficiently.

As all these latter cases had developed among the soldier patients who were quartered in an improvised hospital on a lower troop deck, it was patent that for a thorough disinfection of both men and quarters, the men must be moved ashore and placed in an emergency hospital. Through the efforts of Captain Jackson, assistant surgeon of Volunteers, arrangements with the Japanese officers were readily made to do this, and on the morning of September 10 Contract Surgeon William C. Mabry and Harry C. Gemmill, with two acting hospital stewards and ten privates of the hospital corps and ninety-six patients and contacts, with five days' rations and other supplies, were disembarked with

orders to establish and operate such a hospital until the infection of cholera had been eradicated.

On landing, the entire detachment and the buildings to be used for various hospital purposes were thoroughly disinfected and cleansed. By 4 p. m. all this had been accomplished, quarters assigned and the hospital in complete running order, no untoward effects from the exertion and excitement incident to the transfer having resulted.

Of the ninety-six men so transferred four were attendants who had nursed cases of cholera and ninety-two were being sent home for disability as follows: From dysentery, amebic, chronic, 30; other dysentery, sprue and gastroenteric diseases, 32; venereal diseases, rheumatism, tuberculosis, wounds, etc., 30. Of these a number had had cholera in the islands. Considering the class of patients in the hospital it was almost a certainty that the infection had spread more or less. It was therefore no surprise when three new cases developed ashore on the 12th and three more on the 13th of September. All these men had been isolated on the first appearance of suspicious symptoms and were transferred to the cholera hospital as soon as the diagnosis was clear. With these six men, who were infected aboard ship, the infection terminated, and on the 19th, the regular five days' quarantine having elapsed, the remainder of the detachment re-embarked and on the 20th the *Sherman* resumed her interrupted journey to the states, and after another six days of quarantine at Angel Island was permitted to proceed to San Francisco, arriving October 14, after a trip of fifty-one days.*

THE JAPANESE ANTITOXIN AND TOXIN.

In the treatment of cholera the Japanese are using a blood-serum antitoxin and for prophylaxis a toxin or "cholera vaccine." The blood-serum antitoxin is obtained from a horse immunized to the comma bacillus in much the same manner as that practiced in the preparation of the antitoxin of diphtheria. It is also administered to patients in the same manner as that antitoxin and in doses of from ten to seventy-two grams in twenty-four hours, according to the emergency of the case.

The method employed in the preparation of the prophylactic toxin is not that of Haffkine nor are the reactions in any particular nearly so severe. In Haffkine's inoculations the patients are always so severely affected with fever and pain as to require them to take to bed for from six to twenty-four hours, while in the Japanese this severity is unknown. The toxin is prepared as follows: So much of a pure culture of virulent comma bacilli as can be taken up on a platinum wire with a 0.25 cm. loop is added to 1 gm. of a 0.5 per cent. solution of sodium chlorid; after agitation sufficient to thoroughly distribute the bacilli the solution is placed in a hot-water bath at 60 C. for thirty minutes, then enough acidum carbolicum added to produce a 0.5 per cent. solution of that reagent and the resulting preparation injected at once or preserved in corked and sealed blue-glass bottles. An injection of 1 gm. of this toxin is determined in Japanese laboratories by the usual means, to confer after the second day decided protection if not practical immunity for from four to eight weeks,

the symptoms in case of cholera developing being ameliorated and the prognosis made favorable accordingly. A second injection of 2 gms. seven days after the first and a third of 3 gms. after twenty-one days are determined by the same means to confer immunity to cholera for from fifteen to twenty-four months.

Both the antitoxin and cholera vaccine are prepared and standardized in the "Imperial Laboratory" at Tokyo, of which Kitasato is the chief, and are for the use of public officials only, a sufficient supply for private physicians not being available at this time.

The present epidemic of cholera being the first to occur in Japan, and their toxin and antitoxin now used practically for the first time, there are as yet no published statistics to offer with this article. The Japanese expect to publish full data concerning the treatment in this epidemic at its close, probably about March, 1903.

From official information by Doctor Kikuchi, chief of the Nagasaki quarantine medical staff, we cite the following:

In regard to the antitoxin: At this station we have had a series of thirty-one cases of cholera, all of which have been taken from vessels in quarantine and have received the antitoxin injections, with but one fatality.

In approximately seven hundred cases of cholera in Nagasaki and suburbs up to September 15 the mortality has been about 35 per cent., all cases included; very few, however, have died who received treatment by the blood serum administered in reasonable time. (In the Philippines and Manila the mortality is from 70 to 80 per cent.—M.)

We consider that a case of cholera not in extremes will recover under proper administration of the blood serum.

In regard to the prophylactic toxin or cholera vaccine: All the doctors, directors, nurses, attendants and coolies of this station have received two immunizing injections, and although constantly in contact with the disease, no case of cholera has occurred among us.

On the outbreak of cholera in Nagasaki we determined to immunize all the inhabitants of a small town near this station from which we obtain all our coolies. With this purpose in view we proceeded to that town one morning and inoculated a large number, but did not have enough vaccine to conclude. The afternoon of the same day ten cases of cholera broke out there, six among the non-inoculated, all of whom died, and four among the inoculated, of whom two died. After this day no more cases occurred among the inoculated, although the infection spread among those not inoculated and proved very fatal, owing to the fact that the demand for the antitoxin throughout the empire being so great the laboratory at Tokyo could not supply us enough to successfully combat the infection.

RESULTS OF USE OF ANTITOXIN AND TOXIN.

These items of information decided us to use both the antitoxin on the cholera cases as they developed in our hospital and the vaccine for prophylaxis on all available patients. This was done in the station and cholera hospitals without expense to us for material or the services of Japanese surgeons and nurses as required. For therapeutic and clinical data in regard to the eight cholera patients treated with the antitoxin see Charts and Notes 1 to 8 inclusive.

This series of eight cases gives a mortality of 50 per cent. Of the four cases which terminated fatally, all were very sick men whose ultimate recovery was doubtful without the intercurrent attack of cholera. Of the four cases which recovered Cases 2 and 6 were very severe, and would, in our opinion, have resulted fatally but for the treatment with antitoxin. Cases 3 and 5 were diagnosed on the first appearance of symptoms and were apparently aborted by a comparatively small dose of the antitoxin. Marked amelioration of all symptoms followed

* In all, ten cases occurred among the patients and attendants. Of the four aboard, three died, of the six ashore three died. As a matter of interest only we mention that the focus of this infection can not be satisfactorily traced to the case of the cabin passenger who died at Mariveles Bay. It is very probable that a mild undiagnosed case of cholera occurred in the improvised hospital among the chronic dysentery, diarrhea or by relapse or recurrence in an old cholera case, the exacerbation of symptoms in such a case easily escaping detection. The direct means of spreading the infection was probably a drinking cup at the water cooler in the ward.

the injections in all of the cases, the effect on the diarrhea, vomiting, aphonia and anuria being marked, in Case 4 the urinary function being restored after four and one-half days' suppression. The comma bacillus was demonstrated in all the cases by both the Japanese doc-

might be intelligently administered, took the injections themselves, Dr. Mabry on the 14th and Dr. Gemmill on the 15th of September. With their experiences as a guide thirty men were selected and given the injection on the 16th and fifty-three more on the 17th, the bal-

tors and ourselves by culture tests and successive examinations after the injections of antitoxin showed marked diminution in the numbers of the bacilli present in the stools of all the patients and a complete disappearance of seventeen men being rejected because of their extreme debility.

In all eighty-five men received the injection, charts being prepared showing temperature and pulse rate

appearance after the second injection in the four cases which recovered.

Concerning the prophylactic injections of the toxin or cholera vaccine: There being no data as to the effect of such injections on Caucasians, and fearing to give it to sick men without it, the surgeons in charge, that it every four hours for thirty-six hours. Of these charts only the extremes of pulse and temperature in uncomplicated cases and the average of all charts are here reproduced with general notes. See Chart 9 A, B and C, and Note 9.

The detachment left Japan previous to the time set

for the second and third injections, and as the continuance of the same was not indicated the Japanese officials were loath to furnish so large a quantity from their limited supply as would have been necessary to continue the inoculations. They presented to us enough vaccine, however, to continue the series in the cases of the two surgeons and their three stewards who volunteered to undergo the experiments.

These injections were given to these five men en route to the United States and charts and notes were carefully prepared in each case. These are here reproduced in full, with an average chart added. (See Charts 10 to 15 inclusive and Notes 10 to 15.)

At this date (October 22) no sequelæ have occurred in any case, two of the four convalescents left in Japan have arrived in San Francisco, and the other two are

own Perry who plucked the bandage from her eyes and started her people in an era of unprecedented prosperity.

CHARTS AND NOTES.

CASE 1.—Age 23; diagnosis dysentery, chronic; much emaciated; marked debility; attacked by cholera 10 p. m. September 8; rapidly developed typical collapse of cholera; taken ashore and admitted to cholera hospital 8 p. m. September 9, in dying condition; temperature 98.8 F., pulse 105; marked aphonia and anuria; received 40 gms. antitoxin at 8:30 p. m. At 8 a. m. September 9, temperature 99 F., pulse 110; died 11 a. m., having had no vomiting, defecation or urination since the injection.

CASE 2.—Age 31; physical condition good; diarrhea during night of September 8, 20 stools; isolated aboard ship 6 a. m. September 9; temperature 97.8 F., pulse 82; rice water discharges and vomit during the day, transferred to shore cholera

en route perfectly recovered. In their cases no tumefaction or sequelæ remain and their convalescence has been more rapid than is usually the case. The results obtained by this experience are, of course, very limited, but since cholera has become a live, interesting issue with us, and since the "text-book" methods employed in the islands are so unsatisfactory, anything which promises so much as this antitoxin of cholera should be thoroughly studied.

While it may be a matter of some chagrin that we should be two or more years behind the Japanese investigators who have "in time of peace prepared for war" on cholera, we can not give this progressive new nation too much credit for her achievements, and it should be a matter of pride to us, now that Japan has become a power along all lines and such a close and friendly neighbor to us in the far East, that it was our

hospital 8 p. m.; temperature 96.6 F., pulse 128; received 36 gms. antitoxin 8:30 p.m. the 9th and at 8 a. m. the 10th; patient convalescent September 19; eventually fully recovered.

CASE 3.—Age 24; diagnosis, convalescent after operation for removal of tuberculous cervical glands, physical condition fair; admitted to cholera hospital noon September 12; received 18 gms. antitoxin at 1 p. m.; discharged from hospital September 19, practically recovered.

CASE 4.—Age 46; diagnosis dysentery, amebic, chronic, extreme emaciation and debility, fecal incontinence; admitted to cholera hospital noon September 12; received 20 gms. antitoxin at 2 and 4:30 p. m. the 12th and 2 a. m. the 13th; died at 9:45 a. m. September 17.

CASE 5.—Age 23; physical condition good; admitted to cholera hospital noon September 12; received 18 gms. antitoxin at 1 p. m. the 12th; discharged from hospital, September 19, practically recovered.

CASE 6.—Age 28; diagnosis enterocolitis, chronic, physical

OBSERVATIONS ON PROPHYLACTIC "CHOLERA VACCINE" (TOXIN) INJECTIONS.

Every 4 hours—36 hours

Every 4 hours - 36 hours.

Every 4 hours—48 hours.

condition poor; admitted to cholera hospital 1 p. m. the 13th; received 30 gms. antitoxin at 6 p. m.; convalescent September 19, eventually fully recovered.

CASE 7.—Age 24; diagnosis gastroenteritis, chronic, extreme emaciation and debility; admitted to cholera hospital 2 p. m. the 13th; temperature 98 F., pulse 120; marked aphonia and anuria, the vomiting and diarrhea had ceased; received 20 gms. antitoxin at 6 and 10 p. m. the 13th; died at 4 a. m. September 14.

CASE 8.—Age 27; diagnosis dysentery, amebic, chronic, extreme emaciation and debility; admitted to cholera hospital 3 p. m. the 13th; received 20 gms. antitoxin at 6 p. m. and 25 gms. at 10 p. m.; died at 4 p. m. September 17.

CHART 9.—On account of detailed charts and notes following (see 10 to 15) this series of eighty-five charts is illustrated by extremes of temperature and pulse rates in uncomplicated cases only, with an average chart of the whole series. For the same reason the symptoms are divided into three groups, i. e., *a*, comprising about two-thirds of the cases; some tenderness and pain with slight tumefaction at point of injection, slight sensation of heaviness in frontal region with slight feeling of general depression. *b*. Comprising about one-fourth the cases; marked tenderness and pain, with more marked tumefaction and some discoloration at point of injection; moderate frontal or basilar headache; slight pain in axillary glands and considerable general depression. *c*. Comprising about one-twelfth the cases; marked tenderness and pain with moderate tumefaction and discoloration about point of injection, slight pain in axillary glands, cramping or pains in muscles of arms and legs, some precordial pain, slight nausea and marked though not serious depression. No temperature fell lower than 96 F., or mounted higher than 101 F. (uncomplicated); no pulse lower than 58 or higher than 120 (uncomplicated); and in no case did a needle abscess develop or were sequelæ of any kind remarked. All injections in this series were of 1 gm., given hypodermatically in the left infrascapular region.

Explanatory Note to Charts 10 to 15.—These charts record observations following prophylactic injections of cholera vaccine or toxin according to the Japanese method, i. e., of 1 gm. hypodermatically in the left infrascapular region, 2 gms. seven days later in the right and 3 gms. after twenty-one days in the left infrascapular region, temperatures and pulse rates being recorded every four hours until the reaction completed—thirty-six hours in the first and second (except two of forty), and forty-eight hours in the third. Temperatures drawn in solid lines, pulse rate in dotted lines. No needle abscess occurred; no tenderness or tumefaction persisted more than ten days, and with most careful observations no sequelæ have been detected.

CHART 10.—Contract Surgeon William C. Mabry, U. S. A. First injection, slight tumefaction and discoloration, marked tenderness and pain about point of injection, dull frontal headache, slightly feverish, slight precordial pain and well-marked depression. Second injection, more tumefaction (about 10 cm. in diameter) and discoloration, more pain and tenderness about point of injection, dull frontal headache, looseness of bowels with some griping, feverish and depressed with slight precordial pain and soreness of muscles. Third injection, slight tumefaction, slight pain, but extended area of tenderness about point of injection, slight frontal headache, supraorbital neuralgia and soreness of eye muscles, soreness of muscles of hands and feet, slight precordial pain, feverish, with loss of appetite.

CHART 11.—Contract Surgeon Harry C. Gemmill, U. S. A. First injection, slight tumefaction, marked tenderness and pain about point of injection, dull frontal headache, slightly feverish and depressed. Second injection, more tumefaction (about 10 cm. in diameter), marked tenderness and pain about point of injection, very feverish with some depression. Third injection, very slight tumefaction, slight pain, but extended area of tenderness about point of injection, dull frontal headache, supraorbital neuralgia with soreness of eye muscles, slight cramping of muscles of hands and feet with marked depression.

CHART 12.—Acting Hospital Steward Ami G. Weyant, U. S. A. First injection, slight tumefaction and discoloration, marked tenderness and pain about point of injection, slightly feverish and depressed. Second injection, more tumefaction

(about 10 cm. in diameter) and discoloration, more pronounced pain and tenderness about point of injection, slightly depressed. Third injection, slight tumefaction, marked pain and extended area of tenderness about point of injection, soreness of muscles with "growing" pains in arms and legs, severe headache, loss of appetite and looseness of bowels, with moderate griping.

CHART 13.—Acting Hospital Steward Wm. W. Arbery, U. S. A. First injection, slight tumefaction and discoloration, marked pain and tenderness about point of injection, soreness of arm and leg muscles, slight pain in axillary glands, decidedly feverish but slight depression. Second injection, more tumefaction and discoloration, severe pain and tenderness about point of injection, decidedly feverish and sleepless. Third injection, slight tumefaction, marked pain and extended area of tenderness about point of injection, dull "growing" pains in arms and legs, dull frontal headache, very feverish and nervous, griping of bowels without looseness, nausea, vomiting once.

CHART 14.—Acting Hospital Steward Fred W. Wengenroth, U. S. A. First injection, slight tumefaction and discoloration, marked pain and tenderness about point of injection, slight soreness of arm muscles, dull frontal headache, slightly feverish, vertigo, precordial pains and marked depression. Second injection, more tumefaction and discoloration, marked pain and tenderness about point of injection, aching of arm and leg muscles, slightly feverish with precordial pains and slight depression. Third injection, very slight tumefaction and discoloration, less marked pain but extended area of tenderness about point of injection, "growing" pains of arms and legs, dull frontal headache, slight depression, looseness of bowels with moderate griping.

CHART 15.—*A, B and C* are average charts of the preceding five sets. It will be noticed that each succeeding reaction is longer than the last and contains some symptom that is more severe. In the second the pain, while in no case approaching that of the Haffkine toxin, is more severe and the fever felt more markedly. In the third the headache, tenderness, bowel symptoms and muscular pain are more pronounced, the tenderness in cases extending over an entire side, but the fever, tumefaction and depression being less than in either of the other injections. In no case of the entire number were the symptoms serious even to the extent of alarming the patient himself and none were so affected as to confine him to his bed.

Unethical Pharmaceutical Houses.—To modern pharmacy we owe much and to pharmaceutical methods we shall owe much more in the future, but the profession has no more insidious foe than the large borderland pharmaceutical houses. No longer an honored messmate, pharmacy in this form threatens to become a huge parasite, eating the vitals of the body medical. We all know only too well the bastard literature which floods the mail, every page of which illustrates the truth of the axiom, the greater the ignorance the greater the dogmatism. Much of it is advertisements of nostrums foisted on the profession by men who trade on the innocent credulity of the regular physician, quite as much as any quack preys on the gullible public. Even the most respectable houses are not free from this sin of arrogance and ignorant dogmatism in their literature. A still more dangerous enemy to the mental virility of the general practitioner is the "drummer" of the drug house. While many of them are good, sensible fellows, there are others, voluble as Cassio, impudent as Autolycus and senseless as Caliban, who will tell you glibly of the virtues of extract of the coecygeal gland in promoting pineal metabolism, and are ready to express the most emphatic opinions on questions about which the greatest masters of our art are doubtful. No class of men with which we have to deal illustrate more fully that greatest of ignorance—the ignorance which is the conceit that a man knows what he does not know; but the enthralment of the practitioner by the manufacturing chemist and the revival of a pseudoscientific polypharmacy, are too large questions to be dealt with at the end of an address.—Osler.

ANTI-INFECTIOUS ACTION OF CREDE'S COLLARGOL.

We know a number of familiar antiseptic substances that quickly destroy pathogenic bacteria with which they are brought in contact outside the body. From time to time it has been proposed to introduce such antiseptics into the body in order to directly attack general infections, like puerperal septicemia, acute endocarditis and the like. The substances that exercise such prompt bactericidal effect in the test tube might have like action in the living organism harboring infectious organisms. Unfortunately, the conditions in the living body are so infinitely more complex than in the mixtures of the test tube that we long ago learned not to apply the results obtained in the latter to actual infections, and yet the necessity for efficient and otherwise harmless "internal antiseptics" has led to more or less effort to establish by empirical methods the usefulness of certain substances of this class.

Perhaps Credé's colloid silver (collargol) has acquired as much reputation as a safe internal antiseptic as any. It has been introduced into the body by means of inunction of the unguentum Credé, in pill form, and also by means of subcutaneous and intravenous injections. A large number of the most varied forms of infection, local, general and mixed, and human as well as animal, especially equine, have been treated with collargol in some form or other. The results obtained have been contradictory, some praising colloid silver as a specific remedy against sepsis, others denying it all claim to efficacy. It is absolutely a safe statement that collargol has not been able to stand the test of fire applied to it by clinical experience. The apparently brilliant recoveries ascribed to its use are explainable in other ways. All physicians are familiar with the rapid and sudden, apparently spontaneous changes in the clinical picture of various infections; long-continued septic fevers may suddenly show a drop in the temperature that is followed by recovery without the influence of any medicine.

There has been a most noteworthy dearth of accurate experiments with animals in order to establish definitely the real effect of colloid silver on infections, experiments easily so controlled as to exclude the grave sources of error always attaching to clinical work of this kind. This lack of experimental study is supplied in a large measure by the recent investigation of Cohn¹ in Pfeif-

fer's laboratory in Königsberg. The experiments of Cohn are extensive. They include the study of the bactericidal action of collargol in the test tube in watery solution and when mixed with serum; the actual effect on experimental infections with various bacteria, and the study of the tissues and organs of animals injected. Because of the conclusiveness and uniformity of the results only brief recapitulation is necessary: So early as 45 minutes after its introduction into the circulation colloid silver is no longer demonstrable in the blood because it is deposited as demonstrable precipitate in the organs almost immediately after the injection, and this precipitate does not possess any bacterial action in infections. We believe that these experiments settle the fate of collargol as a specific against sepsis. Its history teaches again the important lesson, too often neglected, that accurate experiments carefully controlled will determine many questions more quickly and more decisively than clinical experience.

PROFESSOR LORENZ.

The great notoriety which the daily press has given to a certain case of congenital dislocation of the hip, recently treated by a distinguished foreign surgeon, would lead one to think that the reduction of a dislocated hip of congenital origin was an unknown and unheard of thing before the arrival of Professor Lorenz, and that the learned professor had introduced a new and wonderful principle in surgery to an ignorant and benighted race. One could not blame the ordinary layman for entertaining such views after reading the extravagant and absurd articles that appeared day after day in the daily papers, but the intelligent members of the profession know that the operation has been repeatedly and successfully performed by many surgeons throughout the country. Those of the profession who are at all familiar with the subject are also aware that the so-called bloodless method was not original with Lorenz, although introduced into Germany and popularized by him, and to him is justly due great credit for the improvement in the method which his genius originated and the perfection of technic which he developed.

However, after all has been said for the bloodless method, it is by no means certain that it is the only method, or even the best method in certain cases. As our knowledge of the pathology of congenital dislocation of the hip increases it is found that in certain cases angular deviation of the neck of the femur, twisting of the upper end of the shaft of the bone, relative displacements of the lesser trochanter, etc., are present conditions which can only be remedied by an open operation, and such operations are constantly becoming more frequent at the hands of the surgeon. While it has been clearly demonstrated by Lorenz, Hoffa, Mikulicz, Schede and others that a large percentage of the cases of congenital dislocation of the hip can be improved or functionally corrected by the bloodless method, it has

1. Centralbl. f. Bakt., 1902, xxxii, 732-752 and 804-809.

also been demonstrated by the same men that in a large number of the cases thus operated on an anatomic reduction of the dislocation is not accomplished, but simply a transposition; or, in other words, the case is transformed from an upward and backward dislocation into a forward dislocation, which corrects the lordosis and does away with the peculiar waddling gait.

Nor can the statement that the bloodless method is perfectly safe and harmless be substantiated by the facts. Lorenz himself reported three deaths from chloroform in 360 cases, or one death to 120 cases. This gives a proportion 20 times as great as the average deaths from chloroform in general surgery, and shows what a severe shock the forcible and extensive laceration of the tissues produces. Fractures of the femur and separation of the upper epiphysis have occurred repeatedly, as well as lacerations of the sciatic nerve, producing permanent paralysis, laceration of the vessels, gangrene of the leg, laceration of the perineum, etc. These accidents have occurred in the hands of the most expert. Further details of such accidents may be found in an article by Heusner abstracted elsewhere in this issue of *THE JOURNAL*.¹ Even in the few cases operated on by Lorenz during his stay in Chicago—and they were cases carefully selected from a large amount of material—there was one case of fracture of the femur, one of extensive hematoma and one of complete laceration of the perineum extending from the vagina into the rectum. For the newspaper unsavory notoriety, however, Professor Lorenz should not be blamed. He is, personally a charming character and a gentlemanly scholar, but was unfamiliar with the ways of this country and the ubiquitous and pestiferous newspaper reporter, and should have been better advised. In departing Professor Lorenz will leave behind him many pleasant memories of a genial gentleman and a master, but it is unfortunate that such events as his visit should be seized on by any as an opportunity to cover themselves with reflected glory.

PHYSICIANS AND LABOR ORGANIZATIONS.

In organizing a physicians' protective association in California recently it appears that inquiries were made by some parties as to its possible affiliation with the American Federation of Labor. The following letter, taken from the *Stockton (Cal.) Independent*, explains the status of medical men in relation to that body, and will be taken, we trust, as conclusive enough to prevent any future suggestions of the kind:

WASHINGTON, D. C., Nov. 26, 1902.

Mr. H. M. Alexander, Organizer A. F. of L., Record Building, Stockton, Cal.

Dear Sir and Brother:—Your favor of November 18 at hand, and contents noted. I beg to inform you that it is against the principles of the American Federation of Labor to issue charters to professional men. The only union which is made up of men engaged in different crafts and calling is federal labor, but even in this it is stipulated that only wage earners shall be ad-

mitted, and inasmuch as doctors, lawyers and professional men are not considered wage earners, they are not eligible to membership in local unions in affiliation with the American Federation of Labor. As a rule they are desirous of becoming members only for political reasons, and if they have any other purpose in view such as would be of benefit to organized labor in every instance it has been found that they can be of as much advantage to organized labor outside of its ranks as they can if they are members, and in most instances even more.

With best wishes, I am fraternally yours,

FRANK MORRISON,

Secretary, American Federation of Labor.

We believe that the secretary of the federation is correct as to the usual motives of professional men in desiring to join his body. The professional advantages would certainly be small, if indeed they could be found, and the embarrassments from the connection in other ways most serious. A little thought will readily demonstrate this to any one who is acquainted with the labor movement and its tendencies; the fact needs no illustration. Moreover, as the secretary says, physicians who wish to be of any advantage to organized labor can do more in this way outside than within its ranks.

On the other hand, we can protect ourselves far better and more consistently with the true spirit of our profession in our own organizations. These must necessarily be essentially different in their objects and methods from the modern labor union or federation, and it is well to keep this in mind. There are, it appears, some among us who think the salvation of the profession is in a course that would not elevate us in public estimation, to state it temperately, and would do no one else any adequate good. The average labor organizer is ready to take in everything from cash girls to school teachers, and it is well that his limitations should be thus authoritatively laid down by his own side.

We have no objections to labor organizations in themselves, and do not arrogate to ourselves any intrinsic superiority over any of our fellow men. There are, nevertheless, certain respectable professional and social traditions that it is well to regard, and one of them is that of the distinction between the learned professions and most other occupations. We shall wrong no one if we cultivate an honorable consideration of the dignity of our profession, and this we can do without detracting from or underestimating the special merits of others.

ENEMIES TO PROGRESS.

The Central Iowa Homeopathic Society at a recent session passed unanimously a resolution expressing its dissatisfaction with the Iowa State Board of Medical Examiners on account of its course in complying with the law and examining candidates for license. It also included an expression of its opinion that a diploma should be all that is required. This shows from what quarters we may look for opposition to the present salutary registration laws, and is indirectly a very obvious reflection on the class of material turned out by the doctor-manufactories in which the said society is

1. See p. 1627.

most interested. The special inciting cause of the resolution was a paper read by the Registrar of the College of Homeopathic Medicine of the State University on the "Present Status of Medical Legislation," and the resolutions, as the *Des Moines News* expressed it, suggest the import of his discourse.

INSURANCE COMPANIES AND TUBERCULOSIS SANATORIA.

The insurance companies of Germany have determined, after a three years' test, that it costs less to support sanatoria for their tuberculous policy holders than to pay the policies of the large number of those who would die sooner without sanatorium treatment. It has been argued that our American insurance companies should follow the example of the German companies, not as a matter of sentiment nor from charitable motives toward their policy holders, but as a safe and conservative business proposition. Here, however, fewer tuberculous subjects, and even subjects with a tuberculous history, succeed in procuring a life insurance policy, whereas in Germany the law prescribes that every laboring man shall have insurance; consequently, a larger number of undesirable risks must be carried, and hence the greater need for sanatoria. From the business standpoint, the advisability of maintaining sanatoria on the part of insurance companies is not as evident, and may be doubtful. At the same time those who are interested will do well to study the arrangement and the management of these German institutions, for the economic motives that originally prompted their instalment also guarantee the highest practical efficiency at the least possible cost.

THE NOBEL PRIZE IN MEDICINE.

A Nobel prize has been awarded, as we recently mentioned,¹ to Major Ronald Ross, the British army surgeon, for notable achievement in medicine. The Nobel prizes, founded by the Swedish millionaire and philanthropist, Alfred Nobel, are awarded annually for the most notable achievements in medicine, science, literature and the greatest service in behalf of peace in the world. The awards in medicine, science and literature are made by certain learned societies in Stockholm. To determine the recipients of prizes of this kind must always be a matter of great difficulty and discrimination, but we believe that the award of a prize to Dr. Donald Ross will meet with the hearty approval of American physicians and investigators. The results of the brilliant investigations of Ross in the etiology of malaria have established the essential rôle of the mosquito in the spread of this disease, a demonstration of direct practical bearing destined to save more human lives and to prevent more human suffering than lies in human power to correctly estimate. To lay bare the complicated methods employed by the parasites of malaria in order to maintain existence was the basis for the development of preventive measures, the central idea of which is to stop malaria-carrying mosquitoes from biting human beings. Truly no better example of the practical value of investigation can be cited than this.

THE PROPOSED VIRGINIA ANTI-KISSING LAW.

It has taken considerably over a hundred years for Connecticut to overcome the reputation given it by a malicious humorist of Tory principles during the Revolutionary War. There are probably those who even now have as their principal mental association with the name of the state the story of the Blue Laws, and the fine for kissing on Sunday. There seems to be some danger that a similar obsession will seize some persons in regard to certain other commonwealths if some measures introduced into their legislatures are correctly reported. In Virginia the proposition is to enact that kissing be permitted only on the certificate of the family physician, and unauthorized kissing by any one with weak lungs or any contagious disease is made a misdemeanor punishable by fine. A similar law is proposed in Georgia, and unless the tendency is checked we may see the example followed in still other legislatures. It is difficult to see how such regulations are to be enforced, as kissing and telling are not generally supposed to go together. However unsanitary the practice, it will continue, and a little risk may only add an extra zest to the performance. Speaking seriously, however, such proposed legislation if offered in good faith is unwise because futile; if not in good faith it is unworthy trifling.

REVIVAL OF THE HEART BY MASSAGE.

Massage of the heart, in case of its stoppage, to revive its movements has been recommended and experimentally demonstrated, but the first successful case of its use in man was reported by Dr. E. A. Starling¹ at a recent meeting of the British Society of Anesthetists. In an operation for appendicitis on a man aged 65 under nitrous oxid and other anesthesia, both pulse and respiration ceased together, and artificial respiration and traction on the tongue failed to revive them. Then the surgeon, Mr. W. Arbuthnot Lane, pushed his hand up through the abdominal wound and grasped the motionless heart through the diaphragm. He squeezed it and felt it start pulsating, though no radial pulse could be felt. Artificial respiration and other restoratives were continued, and in about twelve minutes natural respiration reappeared and the pulse became perceptible at the wrist. The operation was then completed without the use of the anesthetic and the patient made a good recovery, with, however, some diaphragmatic tenderness. This rough-and-ready method and its success in this case is suggestive of important possibilities, and demonstrates that cutting operations in these cases are not essential and can be avoided. The previous failures followed extensive exposures of the heart either by rib resection or incision through the diaphragm, as recommended by Mauclaire (in two cases). This of itself introduces a serious complication, and Lane's success was probably mainly due to his avoidance of this. The case, as the *Lancet* remarks, "justifies us in saying that, if during laparotomy the patient's heart stops, the case should never be abandoned as hopeless until manual compression of the heart through the diaphragm has been performed."

1. Editorial, *Lancet*, Nov. 29.

1. THE JOURNAL, November 29, p. 1401, and December 6, p. 1468.

LITERATURE REFERENCES:

An article in a recent medical weekly consisted of four columns of reading matter and two columns of bibliography. Over two hundred authors were quoted from German, French, Italian, Hollandish and Russian sources. Some twenty of the books and periodicals enumerated were found not to be accessible in the libraries of this country. The article was on a hackneyed subject and the literature to be complete should have included several thousand instead of several hundred references. The writer of this particular paper, who probably has no knowledge of any foreign language, manifestly did not consult the list of authors he referred to; the bibliography was either copied or compiled for him by some one else. This is an extreme example of a common abuse. The motive is dishonest. The pretense is altogether false. The borrowed halo of erudition fits badly. References to literature are of value chiefly to the original investigator and not to the casual reader. The former, however, wants the whole literature, and can find the desired information in an index of his specialty. The latter does not care whether Smith in America, or Müller in Germany, in 1856 or 1902, described this, that or the other case. Haphazard bibliographies, therefore, should be omitted. Seldom do they enhance the value of the ordinary article even when they are honestly compiled and accurate as far as they go. When they consist merely of a list of titles that has not been carefully verified and controlled by the author, they are altogether misleading, and hence worse than useless.

THE TOXIC ACTION OF THYROID EXTRACTS.

Thyroid medication has to some extent passed out of the hands of the physician; as an antifat remedy thyroid tablets are extensively and sometimes dangerously utilized by the laity. To the medical profession thyroid extract is well known as a powerful agent, and there are few of us who would not exercise some caution in its prescription for continuous treatment. The general public does not seem to be aware of its evil possibilities, and individuals occasionally suffer serious results from their ignorance. An instance of this is reported by a correspondent of the *British Medical Journal*, Dr. Stuart Tidey of Montreux, Switzerland. A lady, aged 40, died from cardiac failure which could not be traced to any definite cause during her lifetime. After death her husband asked the physician if he could make use of a large collection of drugs which she had been carrying around with her and using without medical advice. They turned out to be some pounds of thyroid tablets, of which she had, it appears, been taking as many as 8 or 10 a day. The original supply had been sent and recommended by a family nurse to reduce weight, and the patient had kept herself amply supplied from that time on, with the result of producing fatal thyroid poisoning. Thyroid extract, as is well known, may produce an enfeebled action of the heart when taken in excess, and in some cases of idiosyncrasy; it can certainly be classed as a dangerous cardiac depressant under certain circumstances, and Dr. Tidey very properly calls attention to the risks of its too popular utiliza-

tion. He says he has ample evidence that it has become a fashionable drug with the public, for various purposes, and often, it is to be feared, is very ignorantly used. He mentions a case where it was sent to one of his patients to be given to her daughter, for the purpose of making her grow taller. We, as physicians, do not know all about the drug, but our estimation of its powers is apparently not equal to that of the laity. The newspaper information in regard to it is, in instances we have seen, so exaggerated with its scareheads that it is not surprising that the ordinary reader has erroneous ideas. As Dr. Tidey suggests, thyroid extract is a good subject for further investigation as to the special dangers of its long-continued use in ignorant hands. It may be that many more cases of fatality from this cause may be revealed.

Medical News.

ILLINOIS.

Cats Carry Contagion.—The board of health of Rockford, believing that cats are largely responsible for the spread of communicable diseases, has issued an order that in all cases where cats have their habitation in homes where scarlet fever, diphtheria or other kindred diseases are present, they must be killed.

Personal.—Dr. Max F. Clausius, formerly of Barrington, late acting assistant surgeon, U. S. Army, has returned from Fort Huachuca, Ariz., located in Palatine, and taken the practice of the late Dr. Maximilian Muffat.—Dr. Charles R. Parke, Bloomington, the dean of the medical fraternity of the city, who is about to move to Louisville, Ky., is to be tendered a banquet by the McLean County Medical Society.

Physician-Superintendent Desirable.—At the last meeting of the Chicago Medical Society, a resolution introduced by Dr. Isaac A. Abt was unanimously adopted to the effect that the society believed it to be to the interests of the administration of the Cook County institutions, Dunning, that a medical officer be in charge there, as by reason of special training and knowledge in medical matters a more satisfactory administration can be obtained under such a man.

Chicago.

Baby-Farm Ordinance.—The ordinance placing all institutions for the custody and care of infants in Chicago under the jurisdiction of the department of health went into effect December 1.

Personal.—Dr. William F. Jacobs has gone to Vienna for a six months' course of study at the university.—Dr. Jacques Loeb was given a dinner by the faculty of the University of Chicago, November 13. He is soon to assume a chair in the University of California.

Diphtheria Prevalent.—In November 356 cases of diphtheria were reported, an increase of 84 cases, as compared with the figures of the corresponding month of 1901. The 29 diphtheria deaths reported for the week ended December 13 is the highest number recorded in any week since that of March 3, 1900.

Senn Hall Dedicated.—The first of the new buildings of Rush Medical College was dedicated to the purposes of clinical instruction, December 17, with exercises in its large amphitheater. Sir William H. Hingston, Montreal, surgeon-in-chief of the Hotel Dieu Hospital and professor of clinical surgery in Laval University, delivered the dedicatory address.

Whooping cough is reported from many parts of the city. This disease, often regarded as trivial, is, at this season of the year, a most serious affliction, because of the great danger from inflammation of the air-passages. The health department bulletin advises precautions, and says 25 per cent. of those under one year of age die if they contract whooping cough.

Smallpox in Suburb a Menace.—Chief Medical Inspector Spaulding says no new cases of smallpox were reported during last week, and adds:

Hammond, Ind., continues to be a menace to Chicago. They have 53 cases of smallpox, only 11 of which are in hospital; the others

most interested. The special inciting cause of the resolution was a paper read by the Registrar of the College of Homeopathic Medicine of the State University on the "Present Status of Medical Legislation," and the resolutions, as the *Des Moines News* expressed it, suggest the import of his discourse.

INSURANCE COMPANIES AND TUBERCULOSIS SANATORIA.

The insurance companies of Germany have determined, after a three years' test, that it costs less to support sanatoria for their tuberculous policy holders than to pay the policies of the large number of those who would die sooner without sanatorium treatment. It has been argued that our American insurance companies should follow the example of the German companies, not as a matter of sentiment nor from charitable motives toward their policy holders, but as a safe and conservative business proposition. Here, however, fewer tuberculous subjects, and even subjects with a tuberculous history, succeed in procuring a life insurance policy, whereas in Germany the law prescribes that every laboring man shall have insurance; consequently, a larger number of undesirable risks must be carried, and hence the greater need for sanatoria. From the business standpoint, the advisability of maintaining sanatoria on the part of insurance companies is not as evident, and may be doubtful. At the same time those who are interested will do well to study the arrangement and the management of these German institutions, for the economic motives that originally prompted their instalment also guarantee the highest practical efficiency at the least possible cost.

THE NOBEL PRIZE IN MEDICINE.

A Nobel prize has been awarded, as we recently mentioned,¹ to Major Ronald Ross, the British army surgeon, for notable achievement in medicine. The Nobel prizes, founded by the Swedish millionaire and philanthropist, Alfred Nobel, are awarded annually for the most notable achievements in medicine, science, literature and the greatest service in behalf of peace in the world. The awards in medicine, science and literature are made by certain learned societies in Stockholm. To determine the recipients of prizes of this kind must always be a matter of great difficulty and discrimination, but we believe that the award of a prize to Dr. Donald Ross will meet with the hearty approval of American physicians and investigators. The results of the brilliant investigations of Ross in the etiology of malaria have established the essential rôle of the mosquito in the spread of this disease, a demonstration of direct practical bearing destined to save more human lives and to prevent more human suffering than lies in human power to correctly estimate. To lay bare the complicated methods employed by the parasites of malaria in order to maintain existence was the basis for the development of preventive measures, the central idea of which is to stop malaria-carrying mosquitoes from biting human beings. Truly no better example of the practical value of investigation can be cited than this.

THE PROPOSED VIRGINIA ANTI-KISSING LAW.

It has taken considerably over a hundred years for Connecticut to overcome the reputation given it by a malicious humorist of Tory principles during the Revolutionary War. There are probably those who even now have as their principal mental association with the name of the state the story of the Blue Laws, and the fine for kissing on Sunday. There seems to be some danger that a similar obsession will seize some persons in regard to certain other commonwealths if some measures introduced into their legislatures are correctly reported. In Virginia the proposition is to enact that kissing be permitted only on the certificate of the family physician, and unauthorized kissing by any one with weak lungs or any contagious disease is made a misdemeanor punishable by fine. A similar law is proposed in Georgia, and unless the tendency is checked we may see the example followed in still other legislatures. It is difficult to see how such regulations are to be enforced, as kissing and telling are not generally supposed to go together. However unsanitary the practice, it will continue, and a little risk may only add an extra zest to the performance. Speaking seriously, however, such proposed legislation if offered in good faith is unwise because futile; if not in good faith it is unworthy trifling.

REVIVAL OF THE HEART BY MASSAGE.

Massage of the heart, in case of its stoppage, to revive its movements has been recommended and experimentally demonstrated, but the first successful case of its use in man was reported by Dr. E. A. Starling¹ at a recent meeting of the British Society of Anesthetists. In an operation for appendicitis on a man aged 65 under nitrous oxid and other anesthesia, both pulse and respiration ceased together, and artificial respiration and traction on the tongue failed to revive them. Then the surgeon, Mr. W. Arbuthnot Lane, pushed his hand up through the abdominal wound and grasped the motionless heart through the diaphragm. He squeezed it and felt it start pulsating, though no radial pulse could be felt. Artificial respiration and other restoratives were continued, and in about twelve minutes natural respiration reappeared and the pulse became perceptible at the wrist. The operation was then completed without the use of the anesthetic and the patient made a good recovery, with, however, some diaphragmatic tenderness. This rough-and-ready method and its success in this case is suggestive of important possibilities, and demonstrates that cutting operations in these cases are not essential and can be avoided. The previous failures followed extensive exposures of the heart either by rib resection or incision through the diaphragm, as recommended by Maclaure (in two cases). This of itself introduces a serious complication, and Lane's success was probably mainly due to his avoidance of this. The case, as the *Lancet* remarks, "justifies us in saying that, if during laparotomy the patient's heart stops, the case should never be abandoned as hopeless until manual compression of the heart through the diaphragm has been performed."

1. THE JOURNAL, November 29, p. 1401, and December 6, p. 1468.

1. Editorial, *Lancet*, Nov. 29.

lastly in the former chapel of the Charity Hospital. This last-named place was notoriously insufficient, and it was decided to build the present structure, which is situated in the Rue Bonaparte, next to the School of Fine Arts. The amount used in its construction was a little less than \$200,000. The most noticeable parts of the building are a vestibule with busts of celebrated physicians and a painting of Pinel, the celebrated alienist, locking up the irons used for insane patients, a large hall for the special meetings of the academy, with a seating capacity of 110, and which is most artistically decorated in the empire style, different committee rooms, a laboratory and institute for vaccination, special rooms for the library, containing 120,000 volumes. At the meeting held on November 25 the president of the academy, who is chosen every year, Dr. Riche, made a discourse in which he showed the importance of the Academy of Medicine, more especially on account of the new sanitary laws, how such measures as had already been carried out to protect children or to prevent too great a spread of alcoholism were due to the academy. He cited the words of the celebrated philosopher, Descartes: "It is of medicine that one should ask the solution of problems which concern the happiness and grandeur of the human race."

Professor Jaccoud, who is perpetual secretary, as the French put it, made a most eloquent speech, in which he showed how continual the progress of medicine was, and his discourse was very much applauded. The minister of public instruction made a speech also, and the meeting came to an end after the president had conferred the cross of Commander of the Legion of Honor on Professor Jaccoud. There are in all 110 members of the academy, which is divided into the following sections: anatomy and physiology, 10; medicine, 13; surgical pathology, 10; therapeutics and natural history, 10; operative surgery, 7; pathology, 7; obstetrics, 7; public hygiene, legal medicine and medical supervision, 10; veterinary medicine, 5; physics and chemistry, 10; pharmacy, 10, and free associates, 10. There are besides 20 national and 20 foreign associates, 100 national correspondents and 25 foreign correspondents.

Cases of Hereditary Locomotor Ataxia by Babinski.

At a recent meeting of the Medical Society of the Hospitals, Dr. Babinski, physician at the Salpêtrière, described two cases of hereditary locomotor ataxia, and remarked they were more frequent than was generally thought. He presented the two patients to the medical society. One was a young woman 22 years old, having Hutchinson's teeth, and presenting at birth anal ulcerations. For two years she has had lancinating pains, the reflex of the pupils is abolished, and the patellar reflex is weaker on the left side than on the right. The father of this young woman contracted syphilis while her mother was pregnant, and infected her. He suffers himself from locomotor ataxia. Dr. Babinski showed another patient who is fifteen years old. There is no pupillar reaction to light, the patellar reflex is abolished, there are urinary disturbances, lymphocytosis of the medullar liquid, specific choroiditis of the left eye, and symptoms of dementia or meningo-encephalitis. The father of this patient has no knee-jerk; there is Argyll-Robertson's sign and gastric disturbances. This patient was not aware he was suffering from tabes, which his physicians had failed to recognize. Dr. Louques described a family in which the father died of progressive general paralysis, the mother and her two daughters presented symptoms of tabes.

Discussion on the Technic of Gastroenterostomy.

Monprofit of Angiers, Hartmann of Paris, Roux of Lausanne, Pauchet of Amiens, discussed gastroenterostomy at the recent Congress of Surgery. Monprofit has performed gastroenterostomy 101 times. He employed the anterior method of Woelfer 15 times, Von Hacker's posterior method 75 times, and Roux's Y process 13 times. The first he found defective, and of the two others Roux's seemed to be more perfect. This technic takes more time, however, and should be used when the patients are sufficiently strong to stand an operation lasting an hour. Out of 60 operations that Dr. Hartmann has performed for non-cancerous lesions of the stomach, there has been only a general mortality of 16.5 per cent., and since 1900, out of 37 cases there have been only 4 deaths, or 10.5 per cent. Better results are obtained if the patients are sent to the surgeon before they are completely emaciated, and in this respect the patients sent by Dr. Hayem and Dr. Soupault, who have made a special study of stomach troubles, are in much better condition. Hartmann considers it advisable to always make an accurate diagnosis, as he does not consider it necessary to operate on all forms of chronic dyspepsia, and he prefers to use Von Hacker's method rather than

Roux's, as he has never seen any complication arising from what is called a *circulus vitiosus*.

Dr. Roux does not consider that gastroenterostomy suffices in ulceration of the stomach, as cancer may supervene. Excision should be performed in such cases, and contrary to what Hartmann says, profuse hemorrhage commands immediate intervention. Dr. Pauchet, who is a clever young surgeon of Amiens, has performed 33 operations for non-cancerous disease of the stomach, and has had only two deaths. Diagnosis is not so much an indication for operation as the symptoms observed, such as vomiting, hemorrhage, pain, loss of flesh and mechanical disturbances of the stomach. He gives the preference to Roux's method, when the patient is in good condition.

Correspondence.

Malaria in the New Born.

YELLOW PINE, LA., Dec. 13, 1902.

To the Editor:—In THE JOURNAL of July 19, 1902, I noted an editorial, "Malarial Fever in the New-Born." I had in my practice last summer a case in point much clearer than the one you cite. It was as follows:

Mother, white, aged 35, five other children, had had not very severe chills at intervals through the spring and summer. I had not advised quinin because in this woman's case the drug invariably brought on uterine contractions. When called at about 4 p. m., I learned that the patient had had a chill about ten that morning, and one about the same time on each of the two days immediately preceding. Her temperature was then 102. She was in labor. In about an hour she was delivered of an eight-month boy that weighed only four pounds. The little fellow seemed to do very well till he was 40 hours old. At that time he had a light chill, followed by a considerable rise of temperature. This was repeated the next morning. On the third morning he had a hard chill, was very blue for nearly an hour, with extremities very cold. After this chill the temperature in the groin was 103. I then gave quinin in ½-gr. doses till three grains were given before next chill time. I also let the father rub the child well in quinin and lard. The mother also took quinin freely. There was no recurrence of chill or fever in either child or mother. This child I am satisfied was bitten by mosquitoes, but would that account for a chill as early as the second day after birth? W. S. LAWRENCE.

Particulars of a Lawsuit.

CHICAGO, Dec. 11, 1902.

To the Editor:—Referring to the notice in THE JOURNAL, December 6, concerning suit brought against me for damages, allow me to state the facts: During an operation by Dr. Lemke in the year 1898 his patient had a cerebral embolism, followed by a partial hemiplegia. Shortly after that a lawsuit was commenced against Dr. Lemke, and I was included in the suit, on account of the supposed financial relations between Dr. Lemke and myself. I was not present at the time Dr. Lemke operated, and had nothing to do with the case. The case was tried two weeks ago, and when the plaintiff had completed his evidence, and without the presentation of witnesses and without a defense on the part of Dr. Lemke or myself, the judge instructed the jury to return a verdict in favor of the defendants, thus exonerating Dr. Lemke from any blame whatever in the matter.

Very truly yours,

J. B. MURPHY.

Book Notices.

DYNAMIC ASPECTS OF NUTRITION AND HEREDITY. By Frank Hordge. Cloth. Pp. 175. Price, \$1.50 net. New York: Wm. Wood & Co. 1902.

The subject of this volume is such a complex and abstruse one that any criticism of a sensible and philosophic handling of it would seem to be almost impossible. The author has undoubtedly given considerable thought to the subject and has brought out his views in a readable form. It is a work that is certainly worth reading, whether one agrees with the author's reasoning or not. The book lacks an index, which is a defect notwithstanding its very moderate size.

THE AMERICAN TEXT-BOOK OF OBSTETRICS. In Two Volumes. Edited by Richard C. Norris, M.D.; Art Editor, Robert L. Dickinson, M.D. Second Edition, Thoroughly Revised and Enlarged. Vols. I and II. Cloth. 1-p. 547 and 554 Respectively. Colored and Half-tone Plates. Price, Per Set, \$7.00. Philadelphia and London: W. B. Saunders & Co. 1902.

The editor of this excellent work has taken the opportunity of a new edition to have several chapters rewritten. At first thought one would not suppose that a text-book on obstetrics would have to be rewritten every few years to keep up with the times, but such is a fact as regards certain parts. The progress made from researches in chemicobiology, in bacteriology, etc., affects obstetrics almost as much as any other department of medicine. Many of the chapters have been rewritten, so that the work is up to date in every particular. It is fully and beautifully illustrated, and nothing has been omitted that would add to its value as a practical work on obstetrics. The only criticism we feel like making is in regard to its form. We can see no reason for such a book being issued in two volumes. It is not so large but it could be very easily handled in a single book.

A TREATISE ON MASSAGE. Its History, Mode of Application and Effects. Indications and Contraindications. By Douglas Graham, M.D., of Boston. Member of the American Association for the Advancement of Science. Third Edition, Revised, Enlarged and Illustrated. Cloth. Pp. 462. Price, \$4.00. Philadelphia and London: J. B. Lippincott Co. 1902.

The author says in his preface, which is in other respects modest, that the reviewer who thinks that he may weigh in it to save himself the trouble of reading the will be very much mistaken. This is a general truth—e of this work as of many others. In this third edition changes and alterations have been made, and the many additions include entirely new chapters on some subjects. In most respects the work is well brought up to date. The semi-popular style is noticeable even more perhaps than in former editions. The author's practice of heading each chapter with a quotation, sometimes duly credited, is uncommon in scientific medicine. The work will undoubtedly hold its own among the popular treatises on this subject.

LECTURE ON OBSTETRICS. By a Regular Physician. Cloth. Dallas, Tex.: Published by Dr. B. E. Hadra.

This is full of excellent advice addressed in a simple and its circulation among the laity would be of advantage in many respects. We wish, however, that the author had brought it out in a little better form and had been more careful in his proof-reading and had exercised more regard for grammatical construction.

Marriages.

SAMUEL BEEKMAN ALISON, M.D., Carlowville, Ala., to Miss Emma Knox Lide of Montgomery, Ala., November 27.

WILLIAM ALEXANDER GRAHAM, M.D., Durham, N. C., to Miss Anne Cameron Shepard of Edenton, N. C., December 3.

ALDEN ARTHUR KNIPE, M.D., Iowa City, Iowa, to Mrs. Emily Benson Kennedy of Philadelphia, in New York City, November 29.

Deaths.

Henry C. Pearce, M.D. Starling Medical College, Columbus, Ohio, 1863, for five years lecturer on physiology and histology in that institution; one of the founders, and for 27 years an honored member of the faculty of Columbus Medical College, and for more than thirty-five years surgeon of the Pennsylvania lines, died from paralysis at his home in Urbana, Ohio, December 2, aged 69. At a meeting of the physicians of the city, December 3, a committee was appointed to draft resolutions of respect and regret, and it was decided to attend the funeral in a body.

Joseph C. Stone, M.D. St. Louis and Missouri Medical College, 1854, a veteran of the Crimean and of the Civil War, an honored member of the profession, and a member of Congress in 1876, died suddenly at his home in Burlington, Iowa, from heart disease, December 3, aged 73. At a meeting of his colleagues in the Des Moines County Medical Society it was resolved to attend the funeral in a body. Resolutions expressive of their sorrow and respect were also adopted.

Nathan Y. Leet, M.D. University of Pennsylvania, Philadelphia, 1852, a surgeon in the Union Army during the Civil War, and for a number of years surgeon-in-chief to Moses Taylor Hospital, Scranton, died at his home in that city from nervous exhaustion, December 6, after an illness of one month, aged 72.

John M. Krim, M.D. University of Louisville, 1869, president of the Louisville Clinical Society, who had a large practice among the German population of Louisville, died suddenly at his residence in that city, December 10, from angina pectoris, aged 60. The Louisville Clinical Society acted as escort at the funeral.

George D. Blomer, Jr., M.D. Jefferson Medical College, Philadelphia, 1890, a member of the Philadelphia County Medical Society and of the South Philadelphia Medical Society, died suddenly, December 1, from hemorrhage of the lungs, at his home in Philadelphia, aged 38.

Martin B. Billingslea, M.D. University of Maryland School of Medicine, Baltimore, 1874, a member of the American Medical Association, died at his residence in Baltimore, December 9, from sepsis and exhaustion following the removal of a carcinoma, aged 54.

Daniel P. Pease, M.D. Bellevue Hospital Medical College, New York, 1882, house physician for several New York hotels, died in Paris, from typhoid fever, December 7, aged 45.

Judson H. Booker, M.D. College of Physicians and Surgeons, Baltimore, 1879, died at his home in Lottsburg, Va., December 1, after a brief illness, aged 46.

Alonzo W. Daum, M.D. Medical College of Indiana, Indianapolis, 1894, died at his home in Connersville, Ind., from stomach trouble, December 3, aged 34.

Robert E. L. Kincaid, M.D. University of Tennessee, Nashville, 1888, died at his home in Bonham, Texas, December 7, after an illness of only five days.

J. Adelard Bazin, M.D. Ecole de Medecine et de Chirurgie, Montreal, 1864, died suddenly at his home in Haverhill, Mass., from acute gastritis, aged 63.

Harlow J. Phelps, M.D. Marion-Sims College of Medicine, St. Louis, 1899, died at Phenix, Ariz., from hemorrhage, November 25, aged 28.

N. W. Bishop, M.D., died suddenly at his home in Loveland, Ohio, November 19. He was one of the oldest practitioners in Clermont County.

James Windsor Fraser, M.D. University of Pennsylvania, Philadelphia, 1884, died at his residence in Philadelphia, November 27.

Louis E. Krombein, M.D. University of Buffalo, N. Y., 1860, died suddenly at his home in Buffalo, December 7, aged 76.

Robert P. Sweatt, M.D. Galveston (Texas) Medical College, 1873, died recently at his home in Waxahachie, Texas, aged 72.

Samuel K. Crawford, M.D. University of Michigan, Ann Arbor, 1861, died at his home in Chicago, December 1, aged 67.

Henry G. Crump, M.D., died at his home in Pell City, Ala., November 26, from accidental poisoning by chloral hydrate.

Frank L. Hinsdale, M.D. Rush Medical College, Chicago, 1881, of Mill Creek, Utah, died suddenly at Scofield, Utah.

Deaths Abroad.

George Caldwell Stephen, M.D., C.M., McGill University, Montreal, 1887, who afterward went to London and obtained the degrees of L.R.C.P. and L.S.A., in 1889, and that of D.P.H. in 1894, and since that time practiced in London, died at his home in that city, recently.

Dr. W. Rager of Copenhagen, a well-known specialist and writer on orthopedics.—**Dr. N. Feuer**, ex-professor of ophthalmology at Budapest.—**Dr. F. Occhini**, ex-professor of operative medicine at Rome.

State Boards of Registration.

Illinois Examination.—**Dr. J. A. Egan**, secretary of the Illinois State Board of Health, reports the examination held at Chicago, October 15 to 17, as follows: Written examination; number of subjects, 11; questions, 110; percentage required to pass, 75; number examined, 62; passed, 54; failed, 5; withdrew, 3.

Medical Organization.

The Work Before Us.

The *St. Paul Medical Journal* has the following clear editorial on this important subject:

"The coming year will be a most important one for the medical profession of the United States, and we of Minnesota must see to it that our share of the responsibility is not neglected and that the duty which we owe to the rest of the profession of the country is properly performed.

"The Minnesota State Medical Society, at its annual meeting in June, adopted the general plan of reorganization, without a dissenting voice, and thus took the first-step, but the real work is still to come. The county societies must work out the details, and where there are no county societies such must be organized. Some of the county societies have hitherto had little more than a nominal existence, and these must be strengthened, and every

man who is eligible to membership must be personally solicited to join. In some of the more thinly-settled portions of the state it will be necessary for two or more adjacent counties to unite, and where possible a hyphenated name combining the names of the counties should be selected. One thing must be carefully borne in mind by those who take up this work—personalities must not be considered as among the qualifications for membership in the county society. Since admission to the state society, as well as admission to the American Medical Association, can only be obtained through membership in the county organization, such membership is a right which every regular practitioner of non-sectarian medicine can demand, unless good cause can be shown why he is not entitled to it. Grossly unprofessional conduct should be the only ground for exclusion.

"A man who does not belong to his county society must belong to one of two classes: either he is one of those who has voluntarily decided to isolate himself from his fellow practitioners and prefers to lead a selfish, solitary existence, or else he must be considered to be under a cloud on account of his professional misdeeds and unfit for association with his professional neighbors. According to our way of looking at it, the best and fairest plan is to admit to the county society even those who are suspected of being a little loose in their professional conduct, unless their sins have been very open and very flagrant, and by example and influence show them the error of their ways. In this way many a man who is perhaps just on the border line of professional misconduct may be saved and kept straight, who would otherwise go entirely wrong. If, after a few months, it becomes evident that a mistake has been made and that the individual in question is openly violating the rules of professional conduct, it will be an easy matter to prefer charges against him and have him expelled in proper form. He can not then claim that he erred through ignorance or that he was not given a chance. If every county does its duty in this matter, we should have a membership of between twelve and fifteen hundred in the state medical society when it comes together next June; and if every state does the same thing we may expect that the membership of the American Medical Association will jump from eleven thousand to fifty thousand in a single year. It is surely unnecessary to dwell upon the advantages which would result from this complete federation of the American medical profession; they must be apparent to all who will give the matter any thought.

"Let us all join hands and work together for the good of all."

Maury County (Tenn.) Medical Society.

Pursuant to a call of Dr. G. Chris Savage, Nashville, chairman of the committee on organization of the Medical Society of the State of Tennessee, a number of physicians of Maury County assembled in Columbia, December 1, for the purpose of organizing a county medical society. Dr. Hazle Padgett was unanimously chosen temporary chairman and Dr. Otey J. Porter, secretary, both of Columbia. A committee was appointed, consisting of Drs. William B. Harrison, Robert Pillow and Charles A. F. Forgey, all of Columbia, to draft a constitution and by-laws for the society, to report December 15.

Chippewa County (Mich.) Medical Society.

Dr. Beverly D. Harison presided over the meeting of this society in Sault Ste. Marie, December 5, at which organization was effected. Dr. Theodore A. Felch, Ishpeming, councilor for the state medical society, was present and explained the plan of organization, which proposes to include Luce and Mackinac counties. The following temporary officers were elected to serve until the regular election to be held in Sault Ste. Marie, January 1: President, Dr. John R. Bailey, Mackinac Island; vice-president, Dr. Charles J. Ennis, Sault Ste. Marie; secretary, Dr. W. G. Rice, Sault Ste. Marie, and treasurer, Dr. Alexander MacDonald, Sault Ste. Marie.

Butler County (Ohio) Medical Society.

This society met in Hamilton, December 3, for the purpose of passing on the constitution and by-laws suggested for county societies by the American Medical Association. The report of the committee was made and the constitution and by-laws

adopted. Dr. Brooks F. Beebe, Cincinnati, the councilor for the district, was present and explained the new plan of organization. The following officers were elected: Dr. Thomas A. Dickey, Middletown, president; Drs. R. Harvey Cook, Oxford, James Macready, Monroe, and August Schumacher, Hamilton, vice-presidents; Dr. John A. Grafft, Hamilton, secretary, and Dr. James E. Torrence, Hamilton, treasurer.

Monongalia County (W. Va.) Medical Society.

Acting on the recommendation of the West Virginia State Medical Association in regard to the formation of county societies, physicians of Monongalia County met in Morgantown, November 18, and effected a temporary organization, with Dr. William M. Sivey, temporary chairman, and Dr. Richard H. Edmundson, secretary, both of Morgantown. The by-laws of the state medical association governing county societies were read and a permanent organization formed. Dr. Spencer S. Wade was elected president; Dr. William M. Sivey, secretary, and Dr. Haught, treasurer. Drs. Brock, Haught and Sivey were constituted a committee on constitution and by-laws, to report December 2.

Manila Medical Society.

We have been favored by Dr. Richard P. Strong, secretary, with a copy of the "Constitution and By-laws of the Manila Medical Society," just organized. The constitution provides for active, associate and honorary members, and guests. Meetings are to be held monthly. Most of the principles contained in the constitutions and by-laws for state and county societies, prepared by the Committee on Organization of the American Medical Association, are included. Five councilors are provided for, each to serve five years. The functions of the council are, in part, those of a board of censors for county societies, and, in part, those of the council and house of delegates for state societies. It asks to be affiliated with the American Medical Association.

Societies.

COMING MEETING.

Western Surgical and Gynecological Association, St. Joseph, Mo., Dec. 29 and 30, 1902.

North Dakota State Medical Society.—The annual meeting of the society will be held at Bismarck, May 21 and 22, 1903.

Greene County (Ohio) Medical Society.—Dr. Thaddeus A. Reamy, Cincinnati, was the guest of this society at its regular meeting held in Xenia, December 4, and delivered an address on "The Treatment of Abortion."

Calhoun County (Mich.) Medical Society.—The twenty-sixth annual meeting of this society was held at Marshall, December 9. Dr. Louis S. Joy, Marshall, was elected president; Dr. James H. Reed, Battle Creek, vice-president, and Dr. William H. Haughey, Battle Creek, secretary and treasurer.

New York Neurological Society.—The following officers have been elected: President, Dr. Pearce Bailey; vice-presidents, Drs. J. Arthur Booth and Frederick Peterson; recording secretary, Dr. Bronislaus Onuf; corresponding secretary, Dr. Frank K. Hallock, and treasurer, Dr. Graeme M. Hammond.

Northwest Arkansas Medical Society.—This society held its annual meeting at Springdale, December 2. An effort is being made to reorganize this society as "The Medical Society of the Tenth Judicial District of the State of Arkansas." Dr. E. G. McCormack, Prairie Grove, was elected president; Dr. Buchanan Hatchett, Fort Smith, vice-president, and Dr. Frank B. Young, Springdale, secretary and treasurer.

Minnesota Valley Medical Society.—The twenty-third annual convention of this society was held in Mankato, Minn., December 4, Dr. William J. Mayo, Rochester, in the chair. The following officers were elected: Dr. William Jacoby, Mankato, president; Drs. Michael Sullivan, Adrian, Louis A. Fritsche, New Ulm, and Archer C. Jacobs, Elmore, vice-presidents; Dr. Edwin D. Steel, Mankato, secretary, and Dr. George F. Merritt, St. Peter, treasurer. The next meeting will be held at St. Peter, in May, 1903.

University of Michigan Clinical Society.—The clinical staff of the University Hospital, Ann Arbor, have formed a

society. The first meeting was held November 28. Dr. Charles B. Nancrede was elected president, and Dr. Joshua G. R. Manwaring, secretary. Dr. George Dock reported a case of amebic dysentery, with abscess of the liver; Dr. Reuben Peterson showed a patient with an inverted uterus; Dr. Flemming Carrow exhibited a patient with interstitial keratitis, and Dr. E. A. Willis a case of tuberculosis of the pharynx.

NEW YORK ACADEMY OF MEDICINE.

Regular Meetings, held Nov. 20 and Dec. 4, 1902.

The President, Dr. Robert F. Weir, in the Chair.

The November 20 Meeting.

The Harder Variety of Hodgkin's Disease.

DR. WILLIAM S. HALSTED, Baltimore, said that the chief symptoms were enlargement of the lymph glands, and usually also of the spleen, with progressive anemia. In about one-third of the cases the liver is involved. The disease usually begins in the cervical glands. Fever had been noted by most writers, and had been present in all of the 11 cases observed by Dr. Halsted. If the cervical glands on one side only are enlarged, it will usually be impossible to make a diagnosis from inspection alone. The enlarged glands are often the size of a Madeira nut, and their bloodlessness is characteristic. There is usually also a suggestion of translucency. Eight of the 11 cases observed at the Johns Hopkins Hospital had been admitted since 1899, 4 of them this year. Ten of the patients were whites; 8 were males. Only one developed tuberculosis. Of the 8 operative cases 7 were known to be living and apparently in good health; one could not be followed. Tuberculin had been given to all but one of the cases. Dr. Halsted spoke in the highest terms of the microscopic work on Hodgkin's disease done by Dr. Dorothy Reed, one of Dr. Welch's pupils.

Although literature shows 104 cases reported cured, Dr. Halsted said there is no evidence to show that a single one has been cured.

A Rare Affection of the Lymph Glands.

Dr. Halsted then reported in detail a remarkable case, which it was thought might prove to be a new affection of the lymph glands. The patient, an intelligent German, 33 years of age, had been under observation from February to August, 1902. He had been well until eight years ago, when a painful, tender swelling developed high up in the right axilla. The growth was removed at the clinic of Mikulicz, but the pain soon returned and continued ever since. For two years there had been a swelling above the right clavicle, which sometimes became tender, at which times the pain was less acute. The skin over the clavicle and in the supra- and infra-clavicular fossæ was red and thin, and the pectoral muscle appeared to be infiltrated by inflammatory products. In the axilla was a mass similar to the one over the clavicle. Tuberculin was injected on three occasions without producing reaction. Professor Mikulicz had sent an abstract of the man's history, together with the statement that he had not been able to satisfy himself as to the exact nature of this curious case. On March 13 he was operated on, and it was found that the axilla was nearly filled with a myxomatous material; there was a pathologic fracture of the clavicle and a portion of this bone had been destroyed. The axillary vein was thrombosed and there was much connective tissue about the veins of the brachial plexus. Portions of the tissue removed were inoculated into the femoral vein of a dog, and into a cavity made in one femur, with a negative result. On May 9 a supplementary operation was done, and it was found that the clavicle was considerably larger, but the disease had apparently not advanced. When last seen, Sept. 15, 1902, there was no pain in the wound and no evidence of extension of the disease.

Dr. Halsted said he felt sure that this case represented a peculiar inflammatory affection of the lymphatic glands. Although the microscopic appearances of the tissue removed closely resembled those of Hodgkin's disease, the naked-eye appearances were very different.

DISCUSSION.

DR. JOSEPH SAILER, Philadelphia, pointed out the difficulty of drawing positive conclusions in the present state of our

knowledge. One should be cautious about assuming that the tubercle bacilli found in the glands bear a relation to pseudo-leukemia, 1, because these bacilli have been found in other forms of tumor, e. g., carcinoma and sarcoma, and 2, because the lymph glands are specially susceptible to infection by this bacillus. Cultures were made in one of his four cases, and a bacillus was found resembling the tubercle bacillus. The speaker was of the opinion that there were various conditions characterized by enlargement of the lymph glands, due to various etiologic factors, and that some of these conditions would, in the future, be successfully shown to be due to infections with the tubercle bacillus.

DR. H. M. BIGGS expressed the opinion that Hodgkin's disease is an infection, most probably tuberculous, and that several types have been included under this one name.

DR. ARPAD G. GERSTER also firmly believed that Hodgkin's disease was of the nature of an infection, and that the wide variations in the type of the disease explained the contradictory statements made with regard to the effects of treatment.

DRS. B. F. CURTIS and JAMES EWING also discussed the subject.

The December 4 Meeting.

The Need of a Radical Reform in the Teaching of Medicine to Senior Students.

DR. WILLIAM OSLER, professor of medicine in the Johns Hopkins University, delivered an interesting discourse on this topic to a large audience, which was notable for the many eminent medical teachers and academicians present. Dr. Osler said that the work of the first and second years in the medical school had been made exceedingly practical in recent years, but, in his opinion, there should be a change in the conception of how medicine should be taught, and the senior student should be started out at once on his road of life. In the ideal course the student really starts as a practitioner, and observer of disordered machines, with whose structure and orderly functions he has already been made familiar. It is a safe rule not to have any teaching except with a patient as a text, and care should be taken not to teach the student too much; rather give him good methods and a proper point of view, and the other things needful will be gradually added thereto.

A most important reform is demanded in the hospital. In the interest of the medical student, the profession and the public, the hospital authorities should be asked for much greater facilities than are at present enjoyed by the students at the majority of our medical schools. The hospital physician is almost sure to become slovenly unless he is engaged in teaching and is himself taught by his house physicians. The objection is often made that the patients dislike having students in the wards, but this he characterized as entirely fanciful. His own experience in this respect had been exactly the reverse, and it had not been a small one, comprising as it did twenty-five years of ward teaching. With ordinary discretion, and actuated by kindly feelings toward his patients the hospital physician will not experience the slightest difficulty in this respect. Again, in these days when the house staff is so overworked, it is almost impossible to conduct a hospital on modern lines without the help of students in much of the routine work.

At the Johns Hopkins the third-year student learns his medicine only in the out-patient department. The class is divided into three groups. Dr. Osler meets the class in the dispensary, in a specially-built class room, on three mornings each week. During the first part of the year they are taught physical diagnosis and history taking; later they are divided into small groups, and assigned to dispensary cases under the supervision of the out-patient staff. They are allowed to follow their patients, if need be, into the hospital wards, and are encouraged to report on them at stated intervals. There are no systematic lectures on the theory of medicine. The students are given simple ward instruction by him three mornings each week, and Saturday the work of the week is reviewed in the amphitheater, with the presentation of charts and records of important cases, together with the morbid anatomy specimens for the week. In

addition, he meets the fourth-year students one evening each week, and has a quiet talk with them over the clinical events of the week, especially the mistakes and failures, both their own and his. In this way the distance between student and teacher is lessened. While Dr. Osler was not theoretically opposed to systematic didactic lectures, and believed that in some instances the inspiration of a Trousseau would be valuable to the student, he was of the opinion that, for the most part, the ordinary systematic didactic lectures were no longer necessary. At stated intervals the assistants should hold recitations. He desired to plead most earnestly that the same privileges might be enjoyed by medical students in the other medical centers of the country.

DISCUSSION.

PROF. H. L. BURNELL of Harvard University said that while educators generally had watched with the keenest interest the doings at Johns Hopkins University, the conditions there, especially the small classes, made it possible for them to carry out plans of instruction which would not be feasible in other cities. He then described some reforms made at Harvard. Last June the curriculum had been so arranged as to give a minimum of required work and a maximum of elective work. The first year and a half is devoted to anatomy, histology, physiology, physiologic and pathologic chemistry, pathology and bacteriology; the second year and a half is devoted to medicine, surgery, obstetrics, hygiene, pharmacology, dermatology, gynecology, pediatrics, neurology, syphilis, ophthalmology, otology, laryngology, legal medicine and psychiatry. In the fourth year the student is allowed to devote his one thousand hours of time to any subject that he may elect, and in making this choice he is advised by a special committee. He hoped in time Harvard would add still other reforms. One would be to require all students to serve during the fourth year as clinical clerks and surgical dressers in the wards and outpatient departments of a hospital, the work being so arranged that in the first six months practically all of the student's time would be so occupied, while in the last half year it would take either his mornings or afternoons. It is well to encourage research work among the fourth-year students because of the excellent training it gives them. A third method of improving medical teaching is by making section work a prominent feature. To abolish the lecture seemed to him a great mistake.

PROF. ALEXANDER MCPHEDRAN of the University of Toronto insisted that we should ever keep before the public mind the fact that the function of the hospital is three-fold, viz.: 1, to care for the patients; 2, to train nurses for the care of people outside who can not go to the hospital, and 3, to train medical students to care for the poor in various parts of the country who can not come to the hospital. He had found Dr. Osler's plan feasible when his classes numbered fifty or sixty students, but now that there were a hundred or more students it was exceedingly difficult to give them the needed practical instruction. He had found that very few patients, indeed, in hospital objected to the students working there; after all, the patients usually acted as they were expected to do, and where it was the custom for students to be instructed in the hospital the patients rarely objected—indeed, they sometimes thought they were not treated rightly if not given a full share of the students' attention. The law with regard to obtaining a license to practice medicine in Toronto made it necessary for them to continue the didactic lectures, but he believed the fewer of these lectures the better.

DR. E. G. JANEWAY described the situation in New York City, and pointed out that it would be impracticable to turn the large number of students into the wards of the hospitals, and that, moreover, didactic lectures and other modifications of the curriculum are demanded because the students are not specially selected by virtue of a specially liberal preliminary education as at the Johns Hopkins University. There is much room for improvement here in the matter of the hospitals, even the public ones, giving better facilities to students.

DR. W. B. JAMES of the College of Physicians and Surgeons said that, in the matter of the didactic lecture, every teacher should be a law unto himself. In his opinion the amphitheater

clinic still held an important place. He was not at all a believer in electives for the fourth-year students; the whole four years should be devoted to giving a symmetrical view of the entire field of medicine, with all its specialties.

DR. W. GILMAN THOMPSON said that it was possible to greatly overdo laboratory instruction. The aim of a medical school should be to graduate well-balanced practitioners of medicine so far as this can be done in a reasonable time. A great deal depends on whether or not the students have received a college education, on the size of the classes, the relation of the school to the hospital, and last, but not least, what sort of questions the state examining boards would ask of those applying for licenses to practice medicine. He did not favor the extensive use of didactic lectures, nevertheless they are of service in teaching certain general principles, and in filling in the gaps left by bedside instruction. It is impossible to demonstrate all the symptoms and signs of a disease on a particular case—indeed, there are many limitations to such instruction, and it is impossible to so fully control the clinical material as to present the different subjects in accordance with a prearranged system.

DR. E. B. CRAGIN spoke of the difficulties of teaching practical obstetrics to large classes, and said that, having a class of 200, he had decided that it was wiser to divide them up into groups of six and allow each section to live in the maternity hospital for two weeks than to try to teach them all the year by lectures on the theory.

DR. ELLSWORTH ELIOT spoke of the value of didactic lectures to students of surgery in preventing them from becoming confused in studying a subject that was changing so rapidly.

DR. OSLER, in closing the discussion, said that he pleaded for better facilities for utilizing for students the immense amount of clinical material that annually went to waste, and for the closer affiliation of the patient and student. What was wanted was an intimate contact of the student and teacher.

AMERICAN PUBLIC HEALTH ASSOCIATION.

*Thirtieth Annual Meeting, held in New Orleans,
Dec. 8 to 12, 1902.*

President, Dr. Henry D. Holton, Brattleboro, Vt., in the Chair.

The opening address of welcome was delivered by Rev. Max Heller of New Orleans.

After the transaction of routine business, the reading of papers and reports was begun.

Report of Committee on Disposal of Refuse Materials.

This was read by Dr. W. C. Woodward of Washington, D. C., and stated that the present condition of the art of disposal of city refuse had not advanced materially in the last year. Many of the largest cities in America have reduction plans for the extraction of the grease with more or less success. The latest, and in some parts of the country still the most common, method of disposal, namely, that of feeding kitchen garbage to swine, is now earnestly advocated by a prominent health officer, although most ardently opposed by most sanitarians for many years. It is advocated because under many conditions it is not unhealthful if properly conducted, and it is more economical in smaller communities than any other method. The Berlin proposition of converting kitchen garbage into compost has not yet been sufficiently tried. The results with this method in this country do not seem promising, except where the soil is very barren and the cost of labor very low.

Report of the Committee on Animal Diseases and Animal Food.

This report, read by Dr. M. P. Ravenel, Philadelphia, made reference to the experimental work of Ravenel, Mohler, De Jong, Delepine, Orth, Stenstrohm, Fibiger and Jansen, Max Wolff, Nocard, Arloing, Behring, and a number of other investigators. These investigations were sufficiently numerous and harmonious in the results to establish the following conclusions:

1. The bacillus tuberculosis found in human tuberculosis differed greatly in its pathogenic powers as obtained from different cases.

2. Two types of tubercle bacilli might be obtained from man, namely, one which was somewhat difficult to cultivate, which grew slowly, and the bacilli of which are short, stubby, and free from beading—the so-called bovine type; and the second, which was quite easily cultivated, grew rapidly, was longer, thinner, and inclined to show beading and curved forms—the so-called human type.

3. Virulent cultures might be obtained from both of these types, which, when inoculated, according to the methods used by Koch, and on the species of animals specified by him, produced progressive and fatal tuberculosis.

4. The contention that human tuberculosis could not be transmitted to asses, sheep, goats, and especially to cattle, had been completely disproved.

5. Koch's failure to produce tuberculosis in the animals named with bacilli from human sources was probably due to the use of bacilli of low pathogenic powers.

The report then discussed at length investigations as to the transmission of bovine tuberculosis to man. The results of investigations showed:

1. While the bacilli of human tuberculosis were found of feeble virulence for cattle, there was a considerable proportion of cases in which these bacilli were virulent for cattle as well as other animals.

2. Bacilli of both the bovine and human type had been obtained from cases of human tuberculosis.

3. Bovine bacilli introduced into the human tissues by accidental inoculation, if left, multiplied, and produced disease at the point of inoculation, and even recovered after a considerable time with their vitality and virulence unimpaired.

4. Various statistical studies indicated that a considerable proportion of cases of human tuberculosis, and particularly with children, originated from the ingestion of the bacilli with contaminated food.

It appeared to the committee, therefore, that the conclusions of Koch, announced at the British Congress of Tuberculosis, to the effect that bovine and human tuberculosis were different; that human tuberculosis could not be conveyed to cattle, and that man was insusceptible to bovine tuberculosis were disproved, and should no longer have weight with sanitarians. The evidence adduced indicated that greater care should be exercised to prevent infection with bovine tuberculosis, and particularly to guard children from tuberculous milk.

Officers for the Ensuing Year.

The following officers were elected: President, Dr. Walter Wyman, Washington, D. C.; first vice-president, Dr. C. P. Wilkinson, New Orleans; second vice-president, Dr. John L. Leal, Paterson, N. J.; secretary, Dr. Charles O. Probst, Columbus, Ohio; treasurer, Dr. Frank W. Wright, New Haven, Conn.

Officers of the Bacteriological and Chemical Section.

These were elected as follows: Chairman, Dr. H. L. Russell, Madison, Wis.; vice-chairman, Dr. V. A. Moore, Ithaca, New York; secretary, Mr. G. C. Whipple, Brooklyn, New York; recorder, Dr. Henry D. Pease, Albany, New York.

The next meeting will be held at Washington, D. C., in 1903.
(To be continued.)

SANITARY CONFERENCE OF THE AMERICAN REPUBLICS.

Meeting held in Washington, D. C., December 2 to 6, 1902.
(Concluded from page 1543.)

The Mosquito and Yellow Fever.

CHARLES J. FINLAY, M.D., chief sanitary officer of Cuba, answered the question: "Is the Mosquito the Only Agent Through Which Yellow Fever Is Transmitted?" He stated that there can be no cause for considering fomites as a factor in the propagation of yellow fever and that the mosquito appears to be the only insect capable of transmitting yellow fever infection and, furthermore, that the only mosquito which is a natural transmitter of the disease is the *Stegomyia fasciata*, in which he observed certain peculiarities as to the laying of ova and the readiness of renewing its bites whenever the digestion of a previous meal had been completed. On investigation this particular mosquito was found to fulfill all the conditions which have been postulated in the author's theory, and investigations on the human subject have further borne out his hypothesis. He explains that the power of transmitting yellow fever, as exhibited by the *stegomyia*, should not be considered as an additional functional manifestation on the part of this insect, but as a deficiency in the germicidal power of its venom as compared with that displayed by the venom of other blood-sucking insects. The yellow fever germ often passes unharmed into the stomach of the *stegomyia* and continues therein the mos-

quito phase of its existence, while in the case of any other blood-sucking insect it would have been destroyed on inhibition by the venom. So long as the true germ of yellow fever remains unknown, this hypothesis can not be verified under the microscope, but the principle seems to have been confirmed in the case of the malarial parasite which passed unscathed through the buccal cavity of the anopheles and continued to develop in the stomach, while in other species of gnats it reached the stomach already doomed to degeneration and death. The author concluded by saying that no valid reason has been brought forward thus far for supposing that any other insect or any other species of mosquito except the *Stegomyia fasciata* is capable of transmitting yellow fever.

Uncinariasis.

DR. CHARLES WARDELL STILES had made extensive studies of this disease for the purpose of finding a remedy. He explained that the uncinaria produces a condition closely resembling the persistent malaria for which it is almost invariably mistaken. Among other symptoms of the disease the author stated that it created an abnormal and peculiar appetite and suggested that possibly the dirt-eating and pickle-eating habits noticed in some parts of the South might be due to the presence of the hookworm. He urged that the information concerning the malady be spread broadcast, and predicted that under this propaganda a gradual and noticeable improvement would take place in the condition of the "poor whites" of the South.

International Quarantine.

THE COMMISSION appointed at the meeting held in Mexico in January of this year made an exhaustive report regarding the quarantine of certain diseases. It presented resolutions providing that, with reference to yellow fever, the detention of vessels at the port of arrival should not exceed a period of twelve hours for a visit of inspection, counting from the time of the arrival, and of a period not to exceed twenty-four hours for disinfection after the inspection of the passengers and crew.

In regard to bubonic plague a similar resolution was proposed, consist of a sanitary medical inspection in order to obtain knowledge that there are no cholera patients on board the vessel; that there are no persons suspected of suffering from cholera, because some patients have been found suffering from vomiting and diarrhea, in which case it would be necessary to make a bacteriologic examination of the excreta; in placing suspected passengers under vigilance and isolation for any cases that are taken ill, and finally in the isolation of affected patients until entirely recovered.

In regard to bubonic plague a similar resolution was proposed, with this addition: that the disinfection of passengers, after the visit of inspection of the vessel is over and when the passengers are already out of the vessel, should be for affected persons until the disease has entirely disappeared, and for suspected persons until the termination of bacteriologic examination. The period of quarantine or vigilance will be for seven days in case of persons suspected of plague infection, and when a case of this disease is found during the period of detention for the purpose of disinfection, that period should be extended for a time sufficient to carry out the destruction of the rats.

Agents of Infection.

DR. ARTHUR R. REYNOLDS, Health Commissioner of Chicago, offered the following preamble and resolution, which places more or less responsibility on the animal and vegetable source of infection:

Bubonic plague and other diseases are spread by rats, mice and other lower animals, which to a great extent find sustenance in animal and vegetable kitchen wastes, commonly called garbage; therefore, be it

Resolved, That all organic waste or garbage should be kept separately on the premises until it can be removed unmixed with anything else and destroyed.

Election of Officers.

The officers nominated by the Committee on Organization and mentioned in the report of the committee on page 1544 were declared duly elected.

Prophylaxis of Yellow Fever.

DR. GUILLERAS, Cuba, offered the following resolution regarding the mosquito as a factor in the communication of yellow fever:

The measures of prophylaxis against yellow fever shall be based on the fact that up to the present time the bite of certain mosquitoes is the only proven natural means of propagation of yellow fever; that the governments represented in this conference approve the measures employed in Havana for the prevention of the spread of the disease "on land," for the isolation of cases, and the fumigation of buildings, it being understood that said measures are based on the principles enunciated in the first part of this resolution; that the prevention of the importation of this disease by vessels wherein persons actually infected are found must conform to the methods employed on land, yet there are questions concerning the importation of infected mosquitoes that require further study before any decided modification of the quarantine laws can be recommended.

International Sanitary Bureau.

The conference adopted an extended resolution pertaining to the work of the International Sanitary Bureau whose permanent headquarters are to be in Washington. The resolution makes it the duty of the bureau:

To urge all the parties represented in the conference to promptly and regularly transmit to the bureau all data of every character relative to the sanitary condition of their respective ports and territories; to furnish the bureau every opportunity and aid for thorough, careful and scientific study and investigation of outbreaks of pestilential diseases occurring in the territories of the republics; requires the bureau to lend its aid and experience toward the widest possible protection of the public health of each of the republics, in order that diseases may be eliminated and commerce facilitated; and also to encourage and aid or enforce in all proper ways the sanitation of seaports, including the sanitary improvements of harbors, sewerage, drainage of the soil, paving, elimination of infection from buildings, and the destruction of mosquitoes and other vermin.

To carry out the above provisions it was recommended that a fund of \$5,000 be collected by the Bureau of American Republics.

CHICAGO MEDICAL SOCIETY.

Regular Meeting, held Dec. 3, 1902.

The President, Dr. Wm. A. Evans, in the Chair.

Sclerosis of the Mastoid Process.

DR. OTTO J. STEIN reported in detail cases presenting conditions of drug mania, but wherein operative measures revealed an advanced state of osteosclerosis of the mastoid process. He concludes that, as the result of changes going on within the mastoid process, wherein the mastoid cells are gradually being obliterated by the formation of new bone tissue, the symptom of pain may become so persistent and intense as to cause patients to take recourse to the effects of powerful drugs in order to obtain relief from suffering. The character of the pain is described as very deep seated; a dull ache, similar to a slight toothache, being constantly present. At intervals the pain increases to the extent of being neuralgic in character. It is centered mainly back of the ear, in the mastoid region, and thence radiating up toward the side of the head and down into the neck. Noteworthy is the absence of pain in front of the ear. Pressure over the mastoid, usually just back of the meatus, will elicit a sharp sensation of pain.

Dr. Stein holds that removing a core of bone from the eburnated mastoid process is justifiable and productive of prompt relief.

DISCUSSION.

DR. NORVAL H. PIERCE said that if there is such a thing as a primary sclerosis of the process of the mastoid which causes pain sufficient to force an individual to take morphin, etc., it adds a great deal to the difficulty in diagnosis. The literature does not warrant a belief that there is such a sclerosis. There is sclerosing osteitis in the mastoid, but this always follows suppuration in the antrum and the cells in juxtaposition thereto, and is the same process found in other similar bones. Therefore, one should be careful in accepting the conclusion of the essayist, inasmuch as it would be difficult to differentiate between this condition and true hysteria.

DR. WM. L. BALLENGER believes that there are cases of sclerosis of the mastoid attended by pain, but does not think that they are primary, that is, he does not believe a sclerosis of the mastoid exists previous to a suppurative process. He did not understand Dr. Stein to claim that these cases of

sclerosis of the mastoid are primary, but that they might present with marked evidences at the time of the middle-ear disease. In dealing with these cases, one should differentiate between the neurasthenic cases referred to and a central mastoiditis, that is, a mastoiditis limited to the center of the mastoid process, without any extensive degenerative changes in the mastoid in general.

DR. HENRY GRADLE said that a mastoid operation is altogether too large to undertake without positive indications. If suppurative disease of the mastoid is suspected, one may be justified in operating, but where this can be excluded, it does not seem prudent to operate, as operative procedure may result in accidental complications in the hands of the best operators.

DR. STEIN, in closing the discussion, said that he did not state whether this is a primary or secondary condition. He is fully aware that the tissues are such as to lead one to think that the condition is essentially secondary, but he did not presume to answer the question definitely whether it is primary or secondary.

Splenectomy.

DR. J. CLARENCE WEBSTER reported a case of splenectomy. The patient was 37 years of age, family history negative. She gave a history of repeated attacks of malaria during her residence in the South for many years. Twice she was jaundiced, and twice had a severe pulmonary hemorrhage. Twenty-six years ago she had typhoid fever, and when a child was the subject of rheumatism. Her present illness dates back seventeen years, when she observed after the birth of her child a painful, slowly-growing swelling in the right iliac region. Four years ago a laparotomy was performed, and the operator said he found an inoperable tumor connected with her right kidney. When seen by Dr. Webster during the summer, she complained of severe pain in the abdomen, chest, shoulder and the right iliac region, dysmenorrhea, frequent and painful micturition, and shortness of breath. For the past eight years she had very severe colicky pains in the right side, which at times were so intense as to demand the administration of chloroform. After the subsidence of these pains, her urine was very dark, reddish-brown and of strong odor.

Physical examination revealed an emaciated and sickly-looking woman. The skin of the entire body was of a brown color, with here and there patches of intenser pigment. There were in and on the skin innumerable nodules. Examination of her blood showed 4,016,000 red cells, 16,800 whites, and 70 per cent. hemoglobin. Her temperature for the most part was slightly above normal, from 99 to 101 F.

Bimanual vaginal examination revealed a fixed and retroverted uterus, with appendages not distinctly palpable, but fixed and tender, and close to the right side of the uterus, extending to the ilium, and completely filling the right iliac fossa, was a large movable tumor. Examination of the bladder by the Kelly method was negative save a congested area behind the trigone. Catheterization of the ureters revealed a constriction of the right ureter three inches above the bladder orifice, which could be passed with a catheter. The urine obtained from the right ureter contained some blood, 1.3 per cent. of urea, and, microscopically, contained some small squamous and cuboidal cells, with a few hyaline and blood casts. The urine from the left kidney contained no blood or cellular elements, urea 1.7 per cent., and the quantity that was voided during the period that the catheters were left in the ureters (one hour and fifteen minutes) was three and one-half times greater than on the right side.

After treating the patient for a few months on tonics, she was operated on, September 25, and a large tumor was removed, enveloped in dense adhesions, and which was fixed to the brim of the pelvis, adherent to the uterus and its appendages, to the bladder, and also the vermiform appendix. This tumor was found to be a greatly-enlarged spleen. The patient made a very satisfactory recovery, and was exhibited by Dr. Webster. Microscopic sections of the spleen and the cutaneous nodules were also shown.

Funnel Pelvis.

DR. CHARLES B. REED reported an interesting case of funnel

pelvis. May 4, 1900, he was called in consultation to see a patient, aged 19, in her first confinement. In spite of the utmost efforts attempts at delivery failed, and craniotomy was done on the asphyxiated child. In October, 1901, she reappeared, pregnant for the second time, and Cesarean section was found necessary. The child weighed $7\frac{1}{2}$ pounds, and after four weeks the mother left the hospital with her babe in excellent condition.

DISCUSSION.

DR. RUDOLPH W. HOLMES thought that funnel pelvis, taking all types, is not so infrequent as has been generally believed, but absolutely typical funnel pelvis, with normal bim and contracted outlet, is very infrequent. The most frequent type is the generally contracted one, with the contraction most marked at the outlet.

DR. REED said that forceps are most frequently used in these cases to terminate labor after the head is engaged, and failure with forceps means craniotomy, and success with the forceps might mean extensive lacerations of the soft parts of the mother, with the usual results.

The Relation of Gonorrhea to Tuberculosis of the Genito-Urinary Tract in the Male and Female.

DR. DANIEL N. EISENDRATH presented a study of the cases found in the literature and in his own practice, and drew the following conclusions:

1. That in patients suffering from an acute gonorrhea there may be an almost imperceptible transition into a malignant type of tuberculosis.

2. That subacute or chronic gonorrhea may mask the presence of a tuberculosis. That these, as well as the acute form, may act as predisposing and, at times, as exciting causes of tuberculosis.

3. In patients who show evidence of local complications of gonorrhea, such as prostatitis, vesiculitis, cystitis or epididymitis, one should always bear in mind the possibility of tuberculosis and examine the urine for tubercle bacilli, if anti-gonorrheal treatment causes no improvement.

4. In patients with marked tubercular history, an attack of gonorrhea should be carefully watched, and the prognosis be guarded.

5. Gonorrhea, both in the male and female, often prepares the soil for a later invasion of the tubercle bacillus.

DISCUSSION.

DR. A. J. OSCHNER quoted Hunter Robb of Cleveland, who found, in a very large percentage of cases, infection of the tubes, which, in their gross appearance, seemed to be purely gonorrheal in origin.

DR. G. FRANK LYDSTON thought no one would deny that any severe inflammation of a structure so important as the genito-urinary tract would serve as a possible predisposing or exciting cause of tubercular infection. He believes, however, that if gonorrhea is a powerful exciting or predisposing cause of tuberculosis, or so important as the essayist seems to believe, the profession would have a tremendous number of cases to treat of apparently primary tuberculosis of the genito-urinary tract, and that portion of the genito-urinary tract which is most severely affected, the distal portion, should exhibit many cases of primary tuberculosis, but, as a matter of fact, those cases are exceedingly rare.

DR. CHARLES S. BACON thinks the use of the term primary tuberculosis is misleading. He does not understand Dr. Eisen-drath to imply that there was primary tuberculosis, but secondary tuberculosis, that develops in this region as the result of gonorrhea.

DR. F. KREISSL expected to hear the essayist mention the simultaneous primary infection of the genito-urinary tract with gonorrhea and tuberculosis, of which several well-observed cases are on record. He had seen a few. Adenitis, epididymitis and prostatitis, of the type described, ought to arouse suspicion and call for more careful investigation. Inasmuch as primary tuberculosis of the genito-urinary tract is comparatively rare, and its early detection still more infrequent, the well-known relation between this disease and gonorrhea ought

to be a valuable auxiliary means in a possible early diagnosis and radical treatment.

DR. RACHELLE S. YARNOS exhibited a large fibroid tumor of the uterus; also the pregnant uterus, both of which were removed a few hours previous to their exhibition.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Acne.

John V. Shoemaker, in the *Med. Bulletin*, states that hygienic and dietetic regimen should be observed. Exercise in moderation, fresh air and sunlight are beneficial influences. Avoid all indigestible foods and use local means to reduce inflammation. One of the most effective means is bathing the seat of the disease in water as hot as can be borne. The addition of borax or boric acid to the water is recommended. In the early stages of the malady ointments containing lead zinc or bismuth are beneficial. When the disease has reached a chronic form the applications should be of a more or less stimulating character. The gastrointestinal tract must not be overlooked. In order to overcome the sluggish movement of the intestinal canal the following pill should be taken at bedtime:

R. Pil. hydrargyri	gr. xii	75
Podophyllotoxini		
Aloini, aa	gr. i	06
Olei cinnamomi	m. i	06

M. Ft. pil. No. xii. Sig.: One pill at bedtime.

In order to improve the digestion the following mixture should be given after meals:

R. Acidi phosphorici dil.	3v	20
Tinct. cinchonæ comp.		
Tinct. gent. comp., aa	3ii	60

M. Sig.: One teaspoonful well diluted after each meal.

Chloroform in Earache.

According to an abstract in the *Courier of Med.*, a simple, harmless and infallible cure for earache is effected by making a small funnel of stiff writing paper and saturating a ball of cotton the size of a hickorynut with chloroform and drop it into the funnel; place the small end of the funnel into the ear, draw a long breath and then blow the breath into the large end of the funnel; the fumes of the chloroform are thus carried into the ear and all pain ceases at once.

Atropin in Lead Colic.

Adolph Weber, according to an abstract in *Merck's Archives*, states that he has employed atropin in several cases of lead colic due to lead intoxication. At first he uses extract of belladonna in doses of $\frac{1}{4}$ gr. (.015) frequently repeated, but later he has given preference to the alkaloid atropin in dose of 1/60 gr. (.001) to 1/20 gr. (.003). Prompt relief generally follows, with the exception of cases in which opium has been previously administered. In such cases even enormous quantities of atropin remain ineffective, being neutralized by the opium. The atropin should be given hypodermically. No untoward effects have been observed.

Hydrotherapy in Chlorosis and Secondary Anemia.

According to the "System of Phys. Ther." the rules for the treatment of chlorotic and anemic states should be: 1. Avoidance of a reduction of the body-temperature below the normal, therefore, absolutely little abstraction of heat. 2. Increase in the irritability of the peripheral nerve termination, by means of preparatory heat accumulation or heat supply. 3. Vigorous nerve-stimulation by means of water at the lowest possible temperature.

Dr. Frank Billings, in an article on pernicious anemia, states that hydrotherapy applied in the form of high enemas of normal salt solution repeated two or three times in the twenty-four hours is of service. This treatment is based on the

theory that the disease is of probable toxic origin, with the seat primarily in the intestine.

Sedative in Acute Gastric Catarrh.

The following combination is of service in relieving the distress and vomiting in acute gastric catarrh:

R. Bismuthi subcarb.	3v	20
Acidi hydrocyanici dil.	3i	4
Liq. morph. hyd. (1 per cent.)	3ii	8
Mucil. acaciæ	5iss	45
Aq. chloroformi q. s. ad.	5iv	120

M. Sig.: One teaspoonful four times a day (before meals).

Diet in Gonorrhea.

The dietetic treatment of gonorrhea, according to H. Gilman Thompson, consists in avoiding all alcohol and stimulating food and drinking bland diluents. In severe cases, and in cases among young children who have in some manner been infected, a skimmed milk diet should be ordered at first. Later, light farinaceous articles, stale bread and butter, milk and rice puddings should be added. They must avoid acid fruits, all highly seasoned and fried foods, condiments and pastry. Alcoholic drinks in all forms are absolutely prohibited. Malt liquors are especially bad, as they are in all diseases of the urethra, bladder or prostate. No late meals should be taken. By observing these directions troublesome chordee and ardor urinæ, so apt to occur in the first fortnight, may be prevented. Large quantities of such waters as soda, seltzer, apollinaris and two or three quarts of plain water should be drunk. The fluid dilutes the urine, diminishes the danger of cystitis, and has the additional advantage of decreasing the appetite.

Dionin.

Darier, in *Ther. Monthly*, recommends dionin for tracheitis or bronchitis, prescribed in combination as follows:

R. Dioninæ	gr. iii-v	20-30
Quininæ sulph.		
Sodii bicarb., āā.	3ss	2

M. Ft. Chart. No. x. Sig.: One powder three times daily; or:

R. Dioninæ	gr. iii-v	20-30
Ammonii chloridi	gr. v-viii	30-50
Sodii bicarb.	3iiss	10

M. Ft. Chart. No. x. Sig.: One powder three times a day.

Fromme and Heinrich report this preparation to be a valuable substitute in morphinism; its utility being attributed to the fact that it produces no habituation, also in consequence of its ready solubility accumulation is less liable to take place. They claim that the morphin hunger is appeased and is not replaced by hunger for dionin. It is recommended in such cases in doses ranging from gr. 4/5 to gr. 1 (.05-.06). And to replace from 1/3 to 3/5 gr. of morphin he employs a daily total of gr. xv (1.00) of dionin.

Dionin is ethyl morphin hydrochlorate. It is soluble in seven parts of water, two of alcohol, and in twenty of syrup. The usual adult dose ranges from gr. 1/4 to gr. i (.015-.06).

Hot and Cold Water in Eye Diseases.

The employment of hydrotherapeutic measures in the treatment of diseases of the eye are briefly considered, by W. O. Nance, in *Med. Standard*, as follows:

1. Heat and cold are best applied to the eyes by means of moist pads. They are more efficacious when employed in this manner than by means of the coil or bladder, in that their action is more penetrating, and their effect is more germicidal.

2. The application of heat is indicated in degenerative corneal processes—interstitial and phlyctenular keratitis, corneal ulcers, pannus, infected corneal wounds, suppurative panophthalmitis, in iritis and cyclitis, in muscular spasm, and in contusion and ecchymosis of the lids (black eye) to hasten the absorption of extravasated blood.

3. The application should be of the highest temperature the patient can endure (110 to 135) for a period of fifteen minutes, and repeated at intervals of two or three hours for several hours.

4. Cold is indicated in hyperemia and inflammations of the

conjunctiva. In purulent conjunctivitis it is the remedy par excellence. In traumatism, especially those of the iris and lens and in the early treatment of contusions of the lids its employment is of value.

5. In purulent conjunctivitis iced applications may be continuously used for many hours so long as the cornea remains unimpaired, in which instance they are positively contraindicated.

6. Hot applications greatly assist the rapid absorption of various medicaments employed in ophthalmic practice, and when used for this purpose should immediately precede the installations of such solutions.

Medicolegal.

Twelve Thousand Five Hundred Dollars for Injury to Eyes.—The Supreme Court of Rhode Island holds, in the personal injury case of Cummings vs. The National & Providence Worsted Mills, that a verdict for \$12,500 could not be said to be excessive, where a belt parted and one end of it struck a man 51 years of age and earning \$1,000 a year in the eyes with a force sufficient to break the glasses which he wore, driving the glasses into his eyes and displacing the interior parts of both eyes, causing the entire loss of sight in one eye and the loss of distinct vision in the other even at a distance of a few inches, with the probability, according to the undisputed medical testimony, of total blindness in the near future.

State Board of Health and Location of Cemetery.—The Supreme Court of New Jersey holds, in *Dodd vs. Francisco*, that, on appeal of the State Board of Health to reverse the determination of a municipal council and a local board of health respecting the location of a new cemetery, the state board, although acting judicially, is not required to examine witnesses under oath on matters in controversy before it. The matters to be considered by the board respecting the propriety of locating a new cemetery, it says, are of so general and public a nature that they can be decided more intelligently by observation and discussion than by testimony. In this respect the board resembles boards of assessment, whose proceedings involve the exercise of judicial functions, but whose judgment is to be founded on facts obvious to their senses, or ascertained by inquiry and examination; who, although not authorized to call witnesses and examine them on oath, should, as do surveyors and freeholders in road cases, visit the premises in controversy and avail themselves of every accessible means of information likely to aid them in reaching a proper determination. On such an appeal as above stated the State Board of Health may consider a report made by one of its committee on a previous hearing in regard to the same matter. On such an appeal the board is not confined to the determination of sanitary questions. The determination of the board on such an appeal is presumed to rest on proper grounds, and that presumption can be overcome only by the certificate of the board to the contrary, or by clear proof to the contrary in case a rule or order to obtain the board's certificate prove ineffectual.

Liability for Hastening Development of Disease.—The Supreme Court of California holds, in the personal injury case of *Campbell vs. Los Angeles Traction Company*, that an instruction was not erroneous which told the jury that if they found from the evidence that the party suing received the injury complained of by reason of the company's negligence alleged in the complaint, and at the time of the reception of such injury she was suffering from some disease, and they further found that such injury hastened the development of such disease, and that thereby, without the fault of the party suing, her present condition, whatever they might find that to be, had resulted from such injury, then the party suing was entitled to recover such damages as they might determine she had sustained from the injury. The court says that the thing involved was not special damage, requiring special averment, although two or three cases which were cited seemed

to support a contrary contention. Physical suffering and injury caused by violence to the person are the natural and direct consequences of the wrong, and are not in the nature of special damage, which must be particularly averred. Again, it says that the liability of one who commits an assault and battery or other unlawful violence to the person of another is not to be measured by the physical strength of the party injured, or his capacity to endure suffering. One of weak physical structure, or small vitality, or in ill health, has as much right to protection from violence as a robust athlete; and in either case the physical injury, the bodily harm, which is actually caused by the violence, whether he be strong or weak, healthy or sickly, is the natural consequence of the wrong, and need not be specially averred.

1. **Symptoms of Prostatic Hypertrophy.**—Keyes reviews the symptoms and treatment of prostatic hypertrophy at length, and remarks that chronic obstruction of urination is the underlying cause of almost all the symptoms and may be regarded as due to elevation of the internal urethral orifice. Obstruction, however, may exist without symptoms and symptoms without obstruction. As the immediate cause of all the symptoms is congestion, hence to the patient the disease represents only a congestion, while to the surgeon it is an obstruction, an elevation of the urethral orifice. The relief of congestion may be relief of symptoms without regard to the obstruction, but this is purely palliative and is not the function of an operation. Radical treatment consists in permanent relief of the obstruction in the floor of the urethra with little regard to congestion, and this may be accomplished by cauterization or extirpation of the offending mass through a perineal or a suprapubic incision. The elective operation must attack the obstacle most directly and remove it most rapidly, while preventing hemorrhage and providing perfect drainage. Of the operations employed at the present day, the one which most often fulfills these conditions is perineal galvanoprostatomy, or Chetwood's operation. He describes this at length and discusses the other methods, showing the objections to them. Castration and vasectomy, he thinks, are likely to have only temporary effect, and the Bottini operation is a blind one and does not afford proper drainage, while suprapubic prostatectomy appears to be more dangerous than the perineal operation, and possibly does not afford as good drainage. It is more disfiguring and convalescence more delayed. Yet in enormous hypertrophy it may offer greater safety to the patient than a narrow opening and deep perineal wound. Of the two perineal prostatectomies, the Alexander and the Dittel, he thinks that the former is most thorough and satisfactory, but the Chetwood operation is, on the whole, the one that he recommends.

2. **Typhoid in Atlantic City.**—Marvel has studied the conditions and concludes that typhoid fever occurring in Atlantic City is not due to the water-supply or the milk-supply, but is probably an introduced disease.

4. **Inguinal Hernia.**—Hill favors a modification of the Halstead operation, leaving out the cut through the abdominal wall in cases with flabby musculature. He calls attention to certain points in the Halstead operation; first, the incision which is ordinarily made too low down, involving the loose tissues at the upper part of the scrotum. His own incision seldom exceeds 6 cm. in length, and its lower extremity corresponds very accurately with the location of the external ring, which is more quickly recognized by approaching it from above than below. The fibers of the external oblique aponeurosis are then separated to correspond with the length and direction of the incision in the skin, thus at once exposing the inguinal canal, the cord, a few vessels and the sac, covered by infundibuliform fascia. After this is divided, separation of the sac from the cord is accomplished with the utmost ease, and it is drawn up out of the scrotum until its ends are free. Thus gently separated, the oozing will be very slight, a ligature is rarely required, and subsequent ecchymosis seldom seen. He has only met with difficulty in two cases, both of which had previously been subjected to injections by persons claiming to cure rupture without the use of the knife. The method of managing the stump is an important one. It is important, he thinks, to have as complete removal of the sac as possible, and of every particle of slack peritoneum about the internal ring, leaving the visceral face of the internal ring as smooth as possible by amputating the sac high up within the abdomen and leaving no open passages or pouches of peritoneum to invite recurrence. A wet gloved finger is the best instrument for separating and loosening up the abdominal end of the sac, but roughness should be avoided. As the sac will often tear after

being opened, this should be deferred until separation of its inner extremity has been fully accomplished. He has used only absorbable sutures, catgut or kangaroo tendon, though he admits that excellent results have been obtained by others with non-absorbable ones. In the after dressing he does not like to apply collodion gauze directly to the wound, but leaves a little material there to absorb the oozing that may occur, and keeps the collodion at a distance of 1 to 2 cm. from the wound. This is preferable to leaving the gauze beneath the non-absorbable layer of collodion to act as a culture media for skin bacteria at the edges. The dressing should be removed for the first time in three weeks, unless infection occurs, and the patient should then be allowed to get up out of bed, and, as soon as he feels able, to return to his usual vocation.

5. **Hot Water for Vascular Neoplasms.**—For the last two years Wyeth has treated a number of cases of angiomas by injections of water of high temperature, 190 to 212 F. and over. The varieties of tumors thus treated are arterial angiomas (cirroid aneurism), capillary angioma, or mother's mark, and venous angioma or cavernous nevus. No accident has occurred in any of the operations, and the results have been such as to justify recommending the method. He employs a syringe with a metal cylinder and adjustable piston, with needles of varying size, and under ordinary aseptic precautions boiling water taken directly from the boiler is injected into the substance of the tumor. The quantity of water and temperature vary with the size and character of the neoplasm. In arterial and venous tumors of large size the needle is thrust deeply into the mass and from 30 to 60 minims of water are forced out. It is then withdrawn $\frac{1}{2}$ to 1 inch, and the operation repeated until the entire tumor is solidified. The water should be hot enough to immediately coagulate the blood and the arterial tissues, but not to scald and produce skin necrosis. When the tension is sufficiently great to cause a slight bleaching of the integument the injection should be discontinued in that area. In treating capillary nevi or mother's marks of important structures, like the eyelid, nostrils or margin of the lip, a small instrument with a delicate needle should be employed and water a little below the boiling point (about 190) is preferable. Not over two to six minims should be injected in a single puncture, and the treatment should start from the various parts of the periphery, the operator watching closely the effect of the first injections, and after a week or ten days repeating them as may be indicated. Water at a very high temperature is apt to produce sloughing in the capillary variety. In cirroid aneurism, and the large cavernous nevi the water should be boiling and kept at the boiling point while the instrument is being used. For this purpose he advises a long metal instrument, beneath the barrel of which a Bunsen burner is held while the operation is being done. In this way the high temperature of the water is maintained in the syringe. The operations are performed under complete narcosis, and in no instance has there been any painful symptom or septic reaction, with the exception of a single case which passed from observation a few days after the injection and later became infected from a superficial eschar. Suppuration followed, but the general good results were the same as in the other cases. He illustrates his paper with a case, and advises special caution in treating angiomas of the scalp and neck, on account of edema. Not more than five or six ounces should be used in case of cirroid aneurism of large size situated on the parietal bone.

6. **Congenital Hip Dislocation.**—The Lorenz method of treating congenital hip dislocation with special reference to the function of the weight-bearing use of the limb is described by Ashley, one of Lorenz's assistants. The details are too elaborate to be reproduced, but special importance is laid on the functional weight-bearing of the limb as affecting the prognosis. Lorenz believes that the child that walks for nine months with the limb in a stable position, stimulated by use, will have a much better chance than the one who refuses to walk. In double congenital dislocation the child can not walk, but she is allowed a rolling chair and can push herself around, propelling the chair by striking the toes on the floor, thus bringing the limb into activity.

7. Femoral Hernia.—Fowler points out the differences between femoral hernia and psoas abscess, varix, etc., and describes a modification of Fabricius' operation as practiced by Prof. G. R. Fowler. In brief it is given as follows:

1. The incision is planned so as to expose the insertion of that portion of the aponeurosis of the external oblique known as Poupart's ligament, at the spine of the pubes, and the line where that structure blends with the fascial structures of the thigh, as well as the sheath of the vessels at the crural opening.

2. The sac of the hernia is exposed and cleared to its neck.

3. The sac is opened and emptied, after which it is ligated at its neck, and the latter, in suitable cases, is inverted toward the abdominal cavity.

4. The edge of the aponeurosis of the external oblique is forced backward to the level of the upper margin of the horizontal ramus of the pubes, and there sutured to the periosteum and the origin of the pectineus muscle. By this means the space between the bone and the downward projection of the aponeurosis, in which space a femoral hernia forms before making its appearance externally, is obliterated.

The more elaborate technic of the operation is described at length.

8. Edward Jenner.—Dock finishes in this issue his article on Jenner, pleading at the close for a return to the Jenner principles in vaccination, insisting on training and expertness in the operators, the assurance of reliable and safe vaccine material and the necessity of revaccination.

10. Appendicitis in the Female.—The subject of Deaver's article is the connection of appendiceal inflammation in the female, with involvement of the adnexa, and he points out the ways in which this may occur. The symptoms of pyosalpinx due to appendicitis are those of appendicitis in the pelvis, followed by dysmenorrhea and irregular menstruation, sometimes leucorrhea and other symptoms of unilateral pyosalpinx without the indurated feeling of the vagina. There is also no history indicating a gonorrheal infection. The treatment will depend on the location of the pus and the condition of the pain. When the abscess is high enough in the pelvis to be reached by incision in the loin, reflecting the peritoneum from the iliac fossa, it may be opened and evacuated from its lower limits, and washed out and packed with gauze. This operation is advocated only because of the size and situation of the abscess and the infectious nature of the appendiceal pus, which may render complete operation more hazardous. Its scope is necessarily limited, and he has several times had to give up the attempt and open the parietal peritoneum after all. This is especially the case when the appendix, while pointing into the pelvis, is well to the median line, and the great omentum, endeavoring to aid in the formation of a protecting barrier, becomes infiltrated and simulates a mass. In desperate cases of anemia and sepsis the abscess may be evacuated by drawing the cervix well forward or backward and incising the posterior vaginal vault thoroughly, opening the peritoneum, and evacuating the pus; irrigation should not be practiced, and the cavity simply drained with gauze. This is a sort of last resort. Opening of a pelvic abscess due to appendiceal disease is a much more serious matter than the same operation for abscess due to tubal or uterine infection. Pus in the appendix is of virulent nature, and care should be taken to avoid spreading the infection.

11. Vaginal Section in Pelvic Suppuration.—Vaginal incision should be the operation of election, according to Montgomery, when the pelvis, and especially the retrouterine pouch, is the seat of a large collection of pus whether secondary to tubal disease or pelvic hematoma. It should be the only method contemplated when the condition of the patient is so precarious that a severe operation can not be considered, and in such cases should be confined to incision and drainage, leaving radical measures for the future. When the ovaries and tubes are so completely destroyed as to render their retention a menace, the experienced operator will prefer it. He describes the technic:

As a preliminary to the operation, the bowels should be thoroughly evacuated and the lower bowel cleansed by frequent enemas. The vagina should be scrubbed by gauze-wrapped fingers, using first a solution of creolin 7.5 cc. (5ij), tr. sapon. virid. 60 cc. (3ij) to a quart of hot water, followed by the same process with sterile water, and finally with alcohol. With a gauze sponge the vagina and vulva are wiped dry, the cervix seized with a double tenaculum and held forward, the perineum retracted and an incision with scissors or knife made through the posterior vaginal fornix to evac-

uate retro-uterine collections. The cavity is thoroughly irrigated with a hot normal salt solution, and a careful examination made of the pelvic viscera. The tubes and ovaries are easily traced; if either are sacculated they can be readily incised and their contents emptied. The exposed cavity should be thoroughly packed with iodoform gauze. When the distended tubes are not prolapsed they can often be more readily reached through an anterior incision. Through such an opening the fundus uteri can be turned down, the inspection of the ovaries and tubes secured, and proper treatment of diseased conditions instituted.

While he drains less frequently than formerly in abdominal operations he is confident that gauze drainage in the vagina makes convalescence more rapid and the after-results better.

After the incision, anterior and posterior, the fundus is turned forward, and the ovaries and tubes reached over the fundus. This position puts the broad ligament upon a stretch and permits its course to be followed readily so that adhesions of tube and ovary can be easily recognized and torn off with greater ease than when proceeding from above. The uterine arteries are easily seen and can be secured by pressure forceps. The upper part of the ligament should be ligated with chromic catgut. The uterine arteries are likewise ligated and the pelvic cavity packed with iodoform gauze.

The procedure can frequently be greatly expedited by employment of the method introduced by Landau and so extensively practiced by Pryor, which consists in the bisection of the uterus and the removal of the separate halves, which affords additional room for easy manipulation. When the suppurative condition is complicated by the presence of fibroid growths the latter can be enucleated and the size of the mass thus reduced.

The advantages of the vaginal section are: 1. It is regarded as a less serious operation by the patient, who will consequently consent to it at an earlier date, when the chances for her recovery without a sacrificial operation are much more probable. 2. The patient experiences less pain and discomfort, her convalescence is more rapid and she bears on her body no marks of the procedure.

12. Pelvic Bone Necrosis.—The different forms of pelvic suppuration due to disease of the pelvic bones are noticed by Wilson, who speaks particularly of the later effects of infantile Pott's disease on childbearing women. He remarks that the more or less common backache of pregnant women is often in reality the cry for relief of the overburdened spine that had recovered from tuberculosis in childhood, and pregnancy may set up a sort of recrudescence of the early disease. Sacroiliac disease is noticed at length as making more trouble for diagnosis and the more unfavorable prognosis on account of the late period of its recognition. He protests against the prevalent idea of the hopelessness of tuberculous bone disease, which has done more to interfere with complete recovery by postponing rational treatment than anything else.

13. Drainage in Pelvic Disease.—As a general rule drainage is becoming less and less used with greater experience and skill in technic. The complicating conditions which modify this rule in pelvic diseases are abscess in the adhesions, lymph surrounding the affected organs, and the acuteness of the infection, especially the latter. We should consider, however, that pus which is to-day virulent and almost certain to infect the operative wound, may next week be handled with impunity. Acute suppurations of the pelvic organs, either gonorrheal or puerperal, should be allowed to advance as far into the sub-acute stage as is permissible with the safety of the patient before operation. In cases of gonorrheal infections, this advice is safe for any operator to follow, but may be dangerous in respect to puerperal infection. Every case, however, must be studied on its own merits, and when in doubt the decision is generally against drainage. Suppurative disease of the pelvis, such as puerperal abscesses (intrapertoneal), suppurations in the pelvic connective tissue (broad ligaments, etc.), pus in the pelvis as the result of bone or joint necrosis, will always demand drainage, and the sooner established the better. In the first two diseases vaginal drainage is safest and best. Vaginal operations always demand a higher percentage of drainage than other operations, and it is one of the greatest objections to this route of operating. Baldy considers that he drains not more than 5 per cent. of his cases. The temperature and pulse will have to be largely relied on, together with the knowledge that the case is one that might demand drainage. He speaks of the possibilities of infection through the drainage tube, and says that surgeons who dispense with drainage rarely or never see a fistula or infected ligatures. The risks of pelvic surgery are reduced to a minimum, and the best interests of the patient subserved when the drainage tube is dispensed with, especially since it is true that if an error of judgment has been committed the mistake is so readily and safely corrected.

14. **Abdominal Cases.**—The cases reported by Peterson are of splenectomy, Cesarean section, puncture of ovarian cyst, and myomectomy in a pregnant woman.

15. **Abortion.**—Marx discusses the subject of abortion. He speaks of lues, which he considers the most prolific cause, next of the toxemia of pregnancy. He understands by this a total and progressive diminution in the daily excretion of urea without evidence of more than a functional renal lesion, accompanied or not by symptoms of constitutional poisoning. There is a difference, however, in individuals in regard to the amount of excretion of urea; it is just possible that certain women excrete habitually a minimum amount, and this might lead to error. If a patient with a history of repeated abortions presents herself with absence of other disturbing conditions, we should estimate the urea from a 24 hours' specimen. Should this fall much below the average, whether there be systematic symptoms present or not, we must consider this a causal factor in the production of the abortions. These patients must be kept in bed and treated accordingly, until the urea estimate is increased up to and above the normal. Endometritis and allied conditions and complications are also important causes, as well as uterine displacements. For the latter Marx condemns abdominal fixation methods as most reprehensible during the childbearing period. The uterus should be suspended freely and not fixed.

17.—See abstract in THE JOURNAL of October 4, p. 857.

19. **Volvulus.**—Erdmann discusses Gibson's statements in the *Annals of Surgery*, Vol. xxxii, and reports three cases. He remarks on the difficulty of diagnosis in cases of obstruction and the special points indicating volvulus, such as slowness of onset, lack of shock, age of the patient, distension of the abdomen outlined in the coils of the intestine. The high mortality in Gibson's cases when the small intestine was involved is noted, and he remarks that it can only be theorized on. Possibly the great sympathetic supplying the small intestine shares the major portion of the responsibility by inducing a more profound degree of shock. He also asks the question, how many of Gibson's cases were subjected to an artificial anus, as in modern surgery the mortality rate is less in primary excisions of gangrenous small intestine than in those cases where an artificial anus is made in the small intestine. His own cases are given in detail.

20. **Unusual Larval Parasites in Man.**—The species here observed are those supposed to be the *Tenebrio obscurus*, which was ejected by a colored man by coughing, though probably from the esophagus or stomach, and the *Hypoderma bovis*, which was found under the skin of a white boy.

22. **Methylene Blue and Quinin in Malaria.**—Moore and Allison have experimented with these drugs and give the results in detail in tabulated form. Their conclusions are:

1. Methylene blue will destroy malarial parasites in many cases, but is less certain than quinin.
2. Methylene blue is probably most valuable in chronic cases, but has no advantage over quinin.
3. The effects are ordinarily more unpleasant than quinin.
4. It is useful in cases that can not take quinin on account of some idiosyncrasy to it. Its use in cases of pregnancy is undetermined.
5. It is probably valuable in treating hematuric and hemoglobinuric fevers on account of its diuretic action; this has yet to be determined. We have had no chance to test its use in such cases.
6. We believe that quinin is quicker and much more certain and would rely on it rather than on methylene blue.

25. **Sterility.**—The point made by Polk is the extension to the condition of sterility of an accepted procedure. He reports from the literature cases where operations on the adnexa, leaving them apparently in a badly mutilated and non-functionating condition, were nevertheless followed by restoration of function and pregnancy. In one case reported by Baer the appendages on the left were removed entirely, those on the right having been dissected from their adhesions, were in shreds, the tube having been torn off about two inches from the uterus. Fifteen months later the patient gave birth to a child. In another case reported by MacMonagle the right appendages were removed, the ovarian vessels on both sides were ligated and ligatures placed around the left appendages, which were connected with a pus cavity discharging through the rectum. A portion of both

the left appendages had to be left in the stump for anchorage. Three years afterwards the woman gave birth to her first child. He refers to other cases and reports one of his own and emphasizes the possible value of freeing the ovaries and tubes from adhesions in its effect on the subsequent function of the organs. As much normal ovarian tissue is to be left as the diseased conditions will warrant and he would give the ovaries the benefit of the doubt in dubious cases. If the uterus is displaced backwards it should be approximated to its normal position, preferably by shortening the round ligaments. The main point is that where sterility is the leading complaint and perhaps the only one, and the difficulty lies in the condition of the appendages, much can be done for its relief.

26. **Spinal-Cord Tumors.**—Spinal-cord tumors are much more difficult to diagnose than those of the brain, and, as generally understood, they include not only those of the cord itself, but anything that encroaches on the cord, or interferes with its function and anatomy. It is important to distinguish intradural, extradural and intramedullary growths, but Collins finds this distinction can only be approximate. Until recently it was supposed that intramedullary tumors were hopeless, but Abbe has recently published a case where the removal was done successfully. Nevertheless it may be said they are still virtually beyond surgery. Collins reviews the symptoms of spinal tumors, pain, disturbance of the tactile sensibility, motor symptoms, spasticity, with later paralysis, exaggeration of the reflexes, visceral symptoms, and muscular atrophy and bed sores as late manifestations. These symptoms are inconstant and in a measure depend on whether the tumor is intra- or extra-medullary. The main difficulties in the diagnosis of spinal cord tumors are to determine where the tumor is in relation to surrounding structures, that is, whether intra- or extra-dural, and at what segment of the spinal cord it is situated. In intramedullary tumors the paraplegia is usually not so complete, but the great point in the diagnosis between the two forms is pain, which in intramedullary tumor is rarely an initial symptom, but is almost invariably so in tumor of the meninges and often severe. A study of the anesthesia must be made to determine the locality of the tumor and the tendency is to locate it too low, therefore an opening should always be made at the upper end of the supposed tumor, and if not found, a further opening should be made in an upward rather than in a downward direction. The consensus of opinion seems to be that the location of the tumor in the cord is from two to four inches above the uppermost limits of the anesthesia, more often the higher than the lower limit. The widespread area of pain is often confusing, and it must be taken in connection with other localizing symptoms. Intradural tumors are nearly twice as common as extradural ones. The latter may exist a long time without giving rise to symptoms, while the former very early produce symptoms. The favorite location is the dorsal region, the lower and upper ends. Thirty-five of the 70 cases analyzed in this paper were in this region, 15 in the cervical, 13 in the lumbar and sacral, and 6 of widespread distribution. Collins reports 2 cases at length and discusses the statistics and results of the operations. He finds that operation is growing in favor, and when one considers the hopelessness of these cases under medical treatment, it is readily seen that surgical interference is the only hope. The results already obtained prophesy still better success in the future and the importance of early operation is emphasized. If recovery does not occur in two or three months after treatment a further improvement may hardly be expected. Immediately after the operation, however, a temporary accession of paralytic phenomena not due to changes produced in the cord by the tumor itself, but secondary to the trauma of the operation, appears in many cases. While the surgery of the spinal cord offers a very attractive field, still the inadequacy of surgery is very manifest. The operations are as prolonged as formerly, the loss of blood is great and sepsis is about as frequent as ever. Therefore, we can not yet say that the majority of spinal-cord tumors can be operated on with success. The latter part of Collins' paper is devoted to a recapitulation of the published cases in the literature.

27. **Yellow Fever.**—Doty replies to an article written by Dr. Carter of the Marine-Hospital Service holding that vessels are secondarily infected with yellow fever. He criticizes Carter's conclusions mainly on the ground that they are not derived from his personal observation, and, therefore, are not conclusive.

28. **A New Diphtheria Bacilli Stain.**—Schausler has improved on Piorkowski's method of staining by substituting pyronin (Grübler) for eosin. The solutions used for making the stains were as follows:

Filtered solution Löffler's methylene blue.....	10 c.c.
Filtered solution pyronin (Grübler).....	1.5 c.c.
{ Pyronin, 0.5 gram. }	
{ Aque dest. 10.0 c.c. }	
Three per cent. HCl-alcohol.....	0.5 c.c.
{ Alcohol absol. 97.0 c.c. }	
{ HCl. (25 per cent.) 3.0 c.c. }	

To prepare specimen: 1. Make cover-glass smear and fix by passing through a flame three or four times. 2. Drop on to a fixed smear enough solution to cover it and let it stand one minute. 3. Wash thoroughly in running water. Mount in Canada balsam and examine with 1-12 oil immersion lens. Magnify 1,000 times.

The above procedure will show the bodies of the bacilli stained blue while the poles are a bright ruby red.

Pseudo-diphtheria bacilli are smaller and take on only a blue color. The bacilli of Asiatic cholera and plague, when stained by this method, show granular bodies in their interior, but these bodies are not metachromatic like those of the diphtheria bacilli described.

30. **The Phloridzin Test.**—Phloridzin is a drug from which glucose is separated in the course of its passage through the body, as shown by the presence of sugar in the urine after its administration. It is perfectly harmless and shows that under normal conditions the two kidneys have equal functional capacity. Watson and Bailey have experimented with this test, their studies going over a period of seven months, using subcutaneous injections of phloridzin to estimate the average amount of sugar eliminated within a specified time after administration; the rate of the sugar excretion; the effect of ether anesthesia on the renal function, and the value of phloridzin as compared with that of the ordinary methods of urinary examination. The general results of their experimental observations are a confirmation of the claims made for the value of the phloridzin test. When studied in relation to the individual cases, however, certain contradictions and defects became apparent. They find that the average quantity of sugar eliminated in the first half hour after the administration of the drug subcutaneously when the kidneys were normal, was about 45 per cent.; and that the first half hour's elimination is greater than the second half hour's by about .06 per cent. When renal disease exists, the first half hour's quantity of sugar eliminated is, for a series of cases, about one-half as much as that when the kidneys are normal, and there is little difference between the two half hours. The effect of ether anesthesia is to stimulate the kidneys to greater functional activity, but the renal function is not, as judged by the phloridzin test, in any way impaired by the anesthesia. This is true only when the kidneys are normal; when they are diseased, ether fails to stimulate them. There is, moreover, relatively much less sugar eliminated in the first than in the second half hour after phloridzin has been given than is the case when the kidneys are sound, judged by the average results. In a series of cases taken collectively the phloridzin test gives accurate indications of the condition of the renal function and of the existence of renal disease. In a certain number of individual cases, it even appears to be more delicate and discriminating than the ordinary urinary tests, but the relatively large number of instances in this series of observation, in which the reverse of this is true, shows it to be too variable to be trustworthy.

31. **Cryoscopy.**—The method of cryoscopy is described by Bailey. The urine must be obtained by means of the urethral catheter, the blood by a small trocar inserted into one of the prominent veins of the arm, and collected in a perfectly clean test tube. The freezing point is determined by the use of a freezing mixture of cracked ice and salt in which a large glass cylinder or test tube is inserted. This is the receiver for a

smaller test tube, which is to contain the blood or urine, kept from contact with the walls by means of a cork and a rubber band about the bottom of the smaller tube. The thermometer is suspended in the smaller tube through the stopper. A sufficient amount of blood or urine is put in to completely cover the bulb of the thermometer. The liquid should be stirred occasionally and the layer of ice and salt mixed by means of a wire or spiral passing through the stopper. The mercury will first fall to a point where it remains for a short time stationary, after which it will rise to a permanent level—the freezing point. The whole test should take not longer than fifteen to twenty minutes. To briefly summarize, Bailey says:

The results of cryoscopy in renal disease, as reported in the different foreign medical journals, would appear to be of the greatest value, and if by further work in this line its value receives additional corroboration, the surgeon of the future will have a means of diagnosis which will be invaluable in all prospective operations on the kidneys.

32. **Pleurisy in Typhoid.**—Sears reports a case and remarks on the complication, which seems to be one of the rarer ones. It is most common after the first week, while the temperature is still high, but may be delayed until convalescence or even relapse. It may show itself by the usual symptoms of pleurisy, but more frequently its onset is insidious and its presence is only discovered on physical examination. The typhoid bacillus has been demonstrated as the cause in a considerable proportion of cases.

41.—This article has appeared elsewhere. See THE JOURNAL of December 13, p. 1551.

42. **Gliomatosis.**—Eshner first gives a classification of the conditions of the morbid cavities of the spinal axis and their causation, and reports a case which he considers to be one of gliomatosis or syringomyelia of the cervical type. The symptoms had a tendency to unilateral prominence and indicated also involvement of the bulbar nerves.

43. **Gallstones.**—Kerr offers the following deductions: That gallstones are more frequent than commonly supposed, and many cases of supposed chronic stomach trouble are their victims. Tenderness at a point half-way between the right costal cartilage and the umbilicus, elicited either by gentle pressure or by a gentle punch is important as a diagnostic symptom of cholelithiasis or cholecystitis. A proper regulation of hygiene, diet containing a large percentage of albuminous or nitrogenous food, abundance of outdoor exercise, and the use of plenty of water are the best prophylactic measures. The rational treatment of gallstones (after they have formed) is their removal by surgical measures, as no internal medical treatment can be relied on. There is an analogy to some extent between the gall-bladder inflammation and appendicitis; the best time to operate is after the acute attack has subsided, unless septic symptoms demand immediate intervention. The x-ray is not as valuable in locating biliary calculi as it is in diagnosing stones in the kidneys. Cholecystectomy is more in favor than formerly, and the results reported have been rather good.

44. **Nephritic Eye Lesions.**—There is no vascular structure of the eye that can not be affected in kidney disease, neither the retina, conjunctiva, uvea nor the lids. The external muscles also may show pathologic signs directly or indirectly attributable to the nephritic condition. Swelling of the eyelids, particularly the lower ones, is also suggestive of renal trouble. Chemosis or swelling of the conjunctiva is sometimes observed, and when unaccompanied by severe local inflammatory processes, should lead to careful examination of the urine. Recurring subconjunctival hemorrhages in persons over 40 should be considered suspicious, and Nance thinks it is a matter of some importance. Primary iritis occurs in a number of cases, and where no syphilitic or rheumatic history can be clearly demonstrated, renal disease may be looked for. Paresis of the several extrinsic ocular muscles, due to sclerosis of the nerves, or to a hemorrhage at their origin is not infrequent. Diminution in the power of accommodation in those past middle life, requiring frequent change of glasses for new work, is a symptom of well-advanced kidney disease. There is a possible connection between catarrh and kidney disease, though it is not

yet decided. The most important lesions, however, are the intraocular ones demonstrable by the ophthalmoscope, albuminuric retinitis. This never appears until the disease is well advanced and indicates a very unfavorable prognosis. Uremic amaurosis is sometimes confounded with albuminuric retinitis, but differs clinically from it so as to be easily recognized. It is more commonly met with in acute nephritis, though it may occur in exacerbations of a chronic condition.

45. **Paralysis and Damage Suits.**—The point insisted on by Aldrich is careful examination by the examining surgeon, with which he maintains it is impossible for a simulator to succeed.

47.—See abstract in *THE JOURNAL* of November 1, p. 1132.

50. **Tetanus.**—Sweetser remarks on the mortality of tetanus under the ordinary treatment, and reports two cases. The first was one of short incubation and acute development treated by antitetanus serum with chloral and morphin and resulting fatally. The second was that of a girl fourteen years of age who had had an operation for ovarian cyst which had been preceded by a vaginal examination, which he thinks introduced the bacillus into a wound or abrasion. The case was an acute one, but the incubation was rather long, thirteen days. The treatment was morphin during the acute stage to control the pain, $\frac{1}{4}$ gr. doses every four hours, antitetanus serum, which seemed to him ineffective, bromids and chloral. On the fifth day veratrum viride was tried, in addition to gelsemium, with remarkable effects on the convulsions. The vomiting was severe, and the doses were reduced from 8 minims of Norwood's tincture and of the fluid extract of gelsemium to 6 minims every four hours and then every five hours. He then returned to chloral and bromid, but the bad conditions recurred so that the veratrum viride and gelsemium were discontinued and increased. The patient made a good recovery. In the ten days about 17 drams each of Norwood's tincture and of fluid extract of gelsemium were given per rectum, with no effect on the cerebrum and no general depressing effect on the system, this being in marked contrast to the chloral. He reviews the different remedies and their effects, and states that the points which he wishes specially to emphasize are the recovery of a severe case under this treatment, the use of remedies which affected the anterior horns of the spinal cord in directly the opposite way from tetanus toxin, and to call attention to the fact that chloral is a dangerous drug, which is more likely to poison the system in this disease than even in health. To record also the opinion, based on observation, that some of the deaths ascribed to the tetanus poison have really been due to the effects of the remedies used.

52. **Formaldehyd in Diphtheria.**—The treatment here recommended by Donaldson is fumigation of the patient's room by burning either tablets or candles of formaldehyd in the adjoining closet, leaving the door open long enough for the escape of gas into the room or, in preference to this, when possible, to fumigate a room and transfer the patient to it and then fumigate another room and transfer the patient back, one room to be used during the day and the other at night. He tabulates seven cases thus treated, five of them of the ordinary type and two mild, with good results. These are not considered numerous enough for definite conclusions, but are of value as of sufficient importance to report with the hope for a further investigation of a remedy which always holds an important place in the treatment of the disease. He does not say just how much of the gas was allowed in the room, but, of course, the air must have been respirable.

55.—See abstract in *THE JOURNAL* of August 9, p. 329.

57.—*Ibid.*

62. **Myopic Eyes.**—Heine has examined myopic and emmetropic eyes extracted after death, with special reference to the condition of the ciliary muscle and optic nerve entrance. He also has compared them with the eye of the pigeon, which has a different arrangement of muscular fibers. He found that the ciliary muscle of the myopic eye may have a form generally supposed to be found only in hyperopia, and also found a decided difference in the optic nerve entrance. In emmetropic

eyes the nerve fibers run almost directly forward until they reach the lamina cribrosa, when they curve outward and then inward, to enter the retina. In the eye with 10 D. myopia, the fibers of the nasal half of the nerve ran almost straight to the lamina cribrosa and then turned sharply to the temporal side for some distance before turning again to enter the retina, the choroid and the retina being here displaced temporarily over the sclera and lamina cribrosa. In the eye with 15 D. myopia the displacement was still more marked and farther over the disc. The pigment epithelium, however, extended almost to the axis of the optic nerve.

63. **Chestnut-Burr Thorns in the Cornea.**—Meding reports a case where a child had a chestnut burr fall on the eye and eight thorns transferred to the cornea, the points projecting into the aqueous chamber within a very short distance of the iris and lens. An attempt was made to remove one of the thorns, and it was found that the slight pressure made on the cornea brought the thorn points into contact with the iris and lens, and the attempt was unsuccessful. Dr. Herman Knapp advised atropin, rest, and no surgical interference whatever. The advice was followed, with the result that the thorns gradually loosened by slight ulceration about the base of each, and were extracted or absorbed, leaving only three scar points, two so tiny and faint as to escape any but careful scrutiny, one somewhat larger and denser, the latter at the point of attempted removal. He remarks on the aseptic nature of the thorns, the curious tolerance of the cornea, the general absorbent powers of the aqueous for vegetable matter, and the wisdom of retaining thorns as plugs for the holes they made, thus preventing infection; a hint of wide application.

64. **Sympathetic Ophthalmia.**—Gifford reviews the theories of sympathetic ophthalmia, favoring the germ theory and in support of Berlin's assumption of the existence of germs especially adapted for growth in the tissues of the eye. He mentions, as analogous, the peculiarities of the trachoma germ, which affects nothing else than the conjunctiva or possibly the lachrymal sac. In case of sympathetic ophthalmia, however, it is not necessary to assume the existence of a germ especially adapted by nature for growth in the tissues of the eye. The rarity of the disease and the fact that it is practically incapable of propagation from case to case speak against the assumption; but it may be that various species of microbes, after growing within the eye for several days or weeks, may, by a process of natural selection, acquire a certain specific adaptation to the uveal tract, so that, on being carried to the second eye by the blood current, they find there conditions most favorable to their development.

66. **X-Rays in Cancer.**—Robinson's address covers the subject of the treatment of malignant disease with the Roentgen rays, which he considers a very valuable addition to our armamentarium, and says that some cases of advanced epithelioma are incurable otherwise. Many of the cases cured and regarded as inoperable by other means could have been quickly cured in an early stage of the disease, hence physicians should devote proper attention to this disease. The majority of cases so far cured could have been more quickly cured by the knife or caustics, especially the latter. In cutaneous cancer the scar is sometimes better after the ray treatment than after the use of caustics, but, as a rule, caustics are preferable, as their action is definite and there is a saving of time in their use. In cases of cutaneous cancer the rays are a valuable adjunct of other methods, and when the disease is situated around the important blood vessels, it is the only method to employ, except in some cases of disease of the extremities, when amputation should be advised. All cases of mammary carcinoma, except those seen in a very early stage, should be treated by the ray treatment before resorting to the knife, and the rays should also be used in all inoperable cases, and in all cases after amputation has taken place. According to our present knowledge, ray treatment is not curative in internal cancer of any part of the body. To obtain the best results in all cases, there must be no fault in the technic of the operation in order to avoid a serious burn and obtain the desired action on the cancer tissue.

68. Paralysis of the Bowel.—A new sign mentioned by Peters is conduction of the heart and respiratory sounds over the whole bowel in case of paralysis with abdominal distension, associated with inflammatory conditions. This special conduction is not present nor is it met with in distension due to ascitic fluid or tubercular fluid unassociated with acute inflammatory conditions. The facts are: 1. The heart and breath sounds are not heard over the abdomen during health, at all events not below the area of the stomach. 2. They are not heard in non-inflammatory conditions of distension. 3. Their prominence in inflammatory conditions is greatest when the gurgling sounds of peristalsis are entirely absent. The inference is that the condition responsible for the phenomenon is paresis or paralysis of the musculature of the bowel wall due to the inflammatory disturbance. It is, therefore, submitted that if these observations are verified, the sound is a valuable one in the diagnosis of paralysis of the intestines, and has a somewhat important prognostic significance, especially if the paralysis is due to sepsis, as is usually the case.

75. Pistol Shot Wounds.—LaGarde publishes the results of experiments with the Luger and Colt's automatic pistols in use in the Army, and concludes that their stopping power is hardly sufficient, and that surgeons should be guarded in their recommendations of such firearms as efficient military weapons in savage warfare.

1. Stomach Dilatation.—Atony and dilatation of the stomach, according to Saundby, are much more frequent than generally supposed. The powder recommended by Dr. Eric Meinert of Dresden, containing 120 gr. of sodium bicarbonate and 90 gr. of tartaric acid, given in succession, dissolved separately in water, is much more effective in certain conditions than the old stomach powder of 15 to 30 grains of each. He thinks that dilatation is nearly twice as frequent in women as in men, and, according to the alleged causes, neurasthenia and dyspepsia seem to be the leading etiologic factors. He grades the cases as slight, marked and extreme; the slight where the greater curvature does not come below the level of the anterior

superior spine, below that line and half way to the pubis he calls marked dilatation, while anything lower than that he regards as extreme. If the greater curvature does not descend below the umbilicus he does not regard it as a case of dilatation. The various symptoms, pain, vomiting, loss of weight, constipation, flatulence, the condition of the tongue, etc., are noted. He concludes:

1. That atonic dilatation of the stomach is a common condition; that it occurs about twice as often in women as in men, and most frequently between the ages of 20 and 50, and that it is ten times more common than dilatation from obstruction, which generally occurs after 30 years of age. 2. That it is caused by neurasthenia or by any prolonged debilitating illness which may set up neurasthenia. 3. That there are no characteristic symptoms, and no correspondence exists between the amount of dilatation and the severity of the symptoms. 4. That the diagnosis can, in the majority of cases, only be made by the distension of the stomach by CO₂, evolved from 120 gr. of sodium bicarbonate and 90 gr. of tartaric or citric acid. 5. That the prognosis does not depend on the extent of dilatation, but rather on the duration of the symptoms, the general health of the patient and the effect of treatment. 6. The treatment must be mainly that of neurasthenia, supplemented by the use of such drugs and diet as may be indicated by complications, for example, gastritis. 7. Gastroenterostomy often fails to relieve these cases.

2. Stomach Concretions.—Fenwick says that concretions of vegetable matter are much less common than hair balls, and that stones or gastroliths are extremely rare and generally occur in men who have swallowed varnish or like substances. They are usually composed of hardened shellac. Hair balls are most common; there are 24 cases recorded. They generally occur in females, only one case in a male being reported. The youngest was 18 years of age, and the oldest 34 at the time of death. It never seemed to be associated with mental disease, and in several cases it was expressly stated that there was no hysteria or special emotionalism. In the majority of cases it originated in the habit of young girls holding their hair in their mouths while reading or biting the hair when excited. At other times it seemed to be due to the habit that some people have of filling their mouths with any substance with which they happen to be working or it might be due to some eccentricity of which the patient is herself unconscious. In one patient it was the custom to clean her comb with her fingers and then put the little bunch of hair into her mouth instead of disposing of it otherwise. Unless the concretions arrive at a considerable size the symptoms may be slight, if any, but as a rule, however, sooner or later intractable dyspepsia appears, the pain becomes localized to the epigastrium or left hypochondrium and is increased by pressure, and vomiting is seldom absent. Anemia is present, appetite variable, and breath offensive. Diarrhea and constipation alternate. There is a well-marked abdominal tumor often large enough to be visible through the parietes, sometimes globular or outlining the stomach. Its principal feature is its extreme mobility. The duration of the disease averages probably about fifteen years. In most of the recorded cases the concretion was mistaken for malignant growth, but the age and sex of the patient, the duration of the complaint and the physical characteristics of the tumor are the best guide against such errors. Malignant disease in early life is rapidly fatal, but concretions are accompanied for a long time by dyspeptic symptoms and seldom prove fatal in less than ten years. The character also of the tumor is different. If gastric symptoms are lacking there may be confusion with enlarged spleen, floating kidney or a fecal accumulation, and especially if the stomach happens to be dislocated. If the tumor is small it may be possible to bring it up with an emetic, but there is always some danger in this because of frequent secondary ulceration of the stomach or duodenum. Surgery is the only resort if the tumor is large.

3. Dyspepsia.—Rankin describes the acute, atonic, acid and nervous forms of dyspepsia, and gives a diet treatment for the chronic disorders: Breakfast: dry toast or stale bread with butter, milk and cocoa, a boiled or poached egg or white fish; luncheon: fish, fowl, or freshly-cooked meats, a little smoothly mashed potato or purée of vegetables, stale bread or toast, and some form of farinaceous pudding made with milk, or fresh stewed fruit, sweetened with saccharin. In the afternoon he would allow a little stale bread, or toast, with butter and milk or cocoa or tea infused in boiling milk. Dinner should be similar to luncheon, but in the early stages it is safest to forbid red

meat, substituting sweetbread, tripe, calf's head or game. Sleep is often promoted by bread and milk. If stimulants are taken at all, he would only give a little whisky, well diluted in one of the ordinary table waters after luncheon or a little light wine. In certain cases, especially the nervous variety, best results are obtained by giving the food in small quantities at a time more frequently repeated. He emphasizes that the mouth should be carefully inspected, and any decayed teeth attended to. In long-standing cases lavage of the stomach may be of advantage. For antisepsis he has found carbolic acid best. In atonic dyspepsia he finds that in most cases relief is afforded by the administration of a combination of dilute hydrochloric acid, pure carbolic acid, strychnin and ginger, followed by tonic drugs. The use of alkalies before meals to promote acid secretions is only attended with good results in mild and recent cases, and seldom succeeds so well as the acid method described. In acid dyspepsia alkalies are specially indicated, and should be administered two or three hours after food and in Rankin's experience are more efficient if combined with an antiseptic, of which bismuth is one of the best. He would give bismuth salicylate in doses of 10 to 15 gr. or else combine the carbonate of bismuth in 30 to 40 gr. doses, either with salol in 10-gr. doses, sodium sulphocarbonate in 15-gr. doses, or carbolic acid in 2-gr. doses. To these may be added strychnin, ginger or ammonia as before, together with a suitable quantity of some morphin solution if there is much pain. Bismuth salicylate is another valuable remedy. When acidity gains the upper hand, despite the bismuth mixture, sipping a wineglassful of very hot water with 10 or 15 gr. of sodium bicarbonate dissolved may give temporary relief. If farinaceous substances predominate in the diet two or three ounces of malt infusion should be taken with each meal. Whenever there is an excess of HCl in the stomach the diastatic action of the saliva is prematurely arrested, and malt given in this way assists Nature to dispose of the starch. When the urgent symptoms are relieved in atonic dyspepsia, tonics still in combination with antiseptics should be ordered. It is often of advantage after the hyperacidity is overcome to give one or other of the mineral acids combined as for atonic cases, but given before food. In nervous dyspepsia it is desirable to increase the quantity and variety of food as rapidly as possible and get the patient to take as much fat in a digestible form as he can assimilate. The stomach discomfort depends on the nerve exhaustion, and is only a local manifestation of the constitutional state, and the routine methods of acids and alkalies therefore fail. Fermentative processes, however, play a considerable part and antiseptics should be administered. The most reliable drugs are zinc valerianate or arsenic, and he suggests the following formula:

R. Zinc valerianate	3 gr.
Pure carbolic acid.....	2 gr.
Arsenous acid	1/40 gr.
Extract of cannabis indica.....	1/4 gr.

One such capsule to be taken after food three times a day.

Rest from physical work is imperative; change of surroundings, cheerful society, massage and hydrotherapy are advisable.

7. Micro-organisms in Vaginal Secretions.—Bergholm made bacteriologic examination of the vaginal secretion of forty pregnant women at Helsingfors. The reaction was always acid. No micro-organisms pathogenic for animals could be found in any case, no pyogenic staphylococci or streptococci nor colon bacilli.

8. Deportation of Chorionic Villi.—Pöten concludes from study of seven pregnant uteri that the villi may be torn off and swept away to other parts of the body, in the course of a normal pregnancy without pathologic sequelæ.

9. Obstetrics and Gynecology in Sixth Century.—Wegschneider has been preparing a German translation of a work by a Byzantine physician who flourished about 540 A. D. and cites many interesting extracts from the part devoted to obstetrics and gynecology. The original Greek manuscript was not published in book form until 1892.

13. Hydrorrhea Gravidarum.—Fleck describes a case in which the child retained the fetal attitude for months and had not attained the complete use of its limbs when last seen. The knee and elbow were particularly stiff. This condition was

evidently the result of the cramped position in the uterus and may explain certain cases of clubfoot. The symptoms of hydrorrhea usually develop suddenly about the third month, and suggest impending abortion, but the fetus continues its development outside the decidua. The hemorrhages observed from time to time are probably the result of the movements of the fetus eroding the unprotected uterine walls.

14. Extrauterine Pregnancy.—Fernwald reports 17 cases, with 4 deaths. Death occurred the nineteenth day in one case from embolism and one patient was moribund when received. There was pyosalpinx on the other side and fatty degeneration of all the organs in the two other fatal cases.

16. Ureter Fistula or Injury.—Stoeckel reported two years ago 8 cases and now adds 7 more. He finds that the ureter is most liable to be injured during vaginal extirpation of a carcinoma of the cervix. He reviews the etiology, symptoms, diagnosis, prophylaxis and treatment. He implanted the ureter in the bladder in 5 cases, by the intraperitoneal route. The results have been excellent. He describes all his cases in detail.

19. Placenta Previa.—Nearly 200 pages are devoted to this comprehensive study of placenta previa as observed 101 times, or in 3.07 per cent. of 3085 childbirths between 1892 and 1900. Multiparæ were the subjects in 76.15 per cent. and the symptoms were severe in all, while the uniparæ presented only mild cases. Strassmann studies his material from every point of view and draws the conclusion that obstetricians and physicians must strive to prevent placenta previa by ensuring perfect involution of the uterus. Conception should not recur until the uterus announces by the return of menstruation that it has regained full functional capacity. Nursing should be promoted on account of its influence on involution. After weaning the child there should be no conception until menstruation has been re-established. These precautions should be impressed with special urgency on pluriparæ, and particularly after the birth of twins or the occurrence of placenta previa. It may be possible by prophylaxis along these lines to prevent the occurrence of placenta previa in many instances.

24. Cinnamic Acid in Treatment of Tuberculosis.—Krause has been using cinnamic acid according to Landerer's directions during the last two and a half years. He has now a record of 21 cases followed for a sufficient length of time, and the results compel him to commend hetol as a most valuable means for the treatment of tuberculosis of the lungs and larynx. He at first attributed the benefits derived to suggestion as the main factor. But he has found a means of testing the physiologic and anatomic factors at work. This is the study of scraps curetted from a tuberculous lesion in the larynx, as compared with those from patients without cinnamic acid treatment. The tubercles under hetol commenced to grow smaller in the first weeks of treatment, and the leucocytes were found exceptionally numerous at all stages. Young connective tissue soon made its appearance in the tubercle, and in time the whole structure, while retaining its shape, grew smaller and became transformed more or less completely into connective tissue. Notable clinical improvement was soon manifest in every case. In one instance a febrile patient whose temperature had persisted high during several months at a sanatorium found the temperature normal in the first week of hetol treatment and bed rest. Not infrequently all the pathological manifestations vanish except for slight modifications in the breathing sounds. In other cases the portions of lung involved become indurated, and in the severe cases the coarse moist râles vanish and the breathing becomes freer and easier. This method of treatment is peculiarly advantageous for cases too advanced for sanatorium treatment as the disease may be arrested and life prolonged. It must be continued for months or even years in some cases. The number of leucocytes rapidly and progressively increases under the hetol, but not unless injected directly into a vein. He gives the details of his 21 cases. All were improved, 13 nearly and 4 completely cured.

25. Causes of Primary Glaucoma.—Levinsohn ascribes primary glaucoma to a solid enlargement of the ciliary body, especially of its processes. The early clinical symptoms indi-

cate such a lesion, and sections from an eye with subacute glaucoma which he has recently had occasion to study, and others with absolute glaucoma, confirm this assumption.

27. Photography of the Fundus of the Eye.—The photograph is taken by means of a combination of lenses and a flash-light. The results are striking, as shown by photographs of the eyes of a cat.

28. Temporary Partial Amaurosis and Migraine.—Jolly lost an eye from a traumatism in childhood. During his student life he suffered from migraine. In the last few years the remaining eye has exhibited typical attacks of teichopsia, accompanied by migraine. Study of his symptoms has convinced him that this pure unilateral "flimmer" scotoma originates in the optic nerve or the retina of the eye involved.

30. Virchow's Last Illness.—Körte was Virchow's physician. He mentions that when Virchow fell in alighting from a street car one evening last winter (the company claim that he stepped off before the car had quite stopped), the neck of the femur was broken, but this soon healed admirably under appropriate treatment. But the abrupt change in his active life made necessary by the treatment of the fracture rendered him restless and impatient and interfered with sleep, and symptoms of senile degeneration gradually developed. The direct cause of death was a myocarditis, probably atheromatosis of the coronaries, possibly combined with inflammatory processes in the kidneys from a transient cystitis. As long as his mind was clear he confidently expected soon to resume his work. A radiogram of the healed fracture is appended.

32. Clinical Value of Ehrlich's Dimethyl Reaction.—In the tests of this reaction described, it was found that it occurred only in severe forms of disease, but was not specific for any one. It is valuable, as it indicates an aggravation of certain special toxic, or infectious-toxic diseases. It parallels the exacerbation. In Kaziczowsky's experience with enteritis, the test was positive only in cases of tubercular origin.

36. Local Application of Heat.—Gross describes a modification of the thermophore, which Quinke introduced into use in 1896. The present device is a tin tube wound back and forth two or three times and fastened to a sheet of asbestos. The tube is connected with a small closed vessel of water over a lamp, one end entering at the top and the other at the bottom of the boiler. There is thus a continuous circulation of warm water through the coil of tubing. These thermophores may be used to keep bags filled with fine sand at an even temperature, and this combination is proving remarkably beneficial in cases of subacute sciatica, lumbago, old spondylitis and especially of gastric ulcers. To prevent the sand from shifting in the bags they can be basted to divide the bag into four long pockets, but it is more pliable without this. The local sweating is one of the benefits of the measure, as it promotes elimination and absorption of pathologic products. In the treatment of chronic exudates the weight of the sandbag may be a factor in the benefit derived.

38. Prurigo Lymphatica.—Buschke describes in detail three cases observed at Lesser's clinic in which prurigo was evidently connected with an affection of the lymphatic system. The patients were 22 to 58 years old and the localization was more diffuse than in Hebra's prurigo. In all the cases certain lymph glands and the spleen were enlarged, but there was no lymphocytosis. Otherwise the cases suggested pseudoleukemia. There were no indications of tuberculosis. A few similar cases have been reported with and without hypertrophy of the spleen. In one published by Blaschko the prurigo developed after a lymphosarcoma in the shoulder had been noticed, and it retrogressed after the neoplasm had been extirpated. There was recurrence later of the growth in the cicatrix and the prurigo and itching reappeared with it. Examination of 5 patients with classic prurigo and 6 with scrofula failed to disclose anything abnormal in the glands or spleen. Lymphatic prurigo is probably caused by some abnormal cell products. The abnormal chemistry of the cells may be a congenital condition, which would explain its rebellious and recurring character. Further study is needed of the cutaneous sensory neuroses observed

associated with internal affections, such as internal cancer, chronic intoxications, echinococcus and recent malaria, to note whether the dermatosis belongs to the prurigo or the urticaria group. The lymphatic prurigo described above has never been examined postmortem. There is a possibility that it may yet prove to be a tuberculous affection.

39. Inoculation Metastasis of Cancer.—Brieger has seen a case similar to that described by Olshausen in No. 42, and reports recent attempts to inoculate animals with carcinoma. He prepared the animals by injections of human blood as for the biologic blood test, and then transplanted still warm carcinoma tissue into the anterior chamber. Pannus developed after this transplantation in a rabbit that had been injected previously with 60 to 70 c.c. of blood from human placenta. The pannus gradually retrogressed, and the carcinoma tissue was dissolved until after three months there is now merely a slight defect in the cornea with no traces of a pathologic lesion. In other animals prepared in the same way scraps of chancre implanted in the cornea were similarly absorbed without a reaction. Experiments in this line on dogs and monkeys are now in progress.

40. Malignant Lymphoma.—A case of lymphoma malignum associated with tuberculosis is described by Spijarny, confirmed by the autopsy findings. The general appearance and heredity suggested tuberculosis, but no symptoms indicated it until a few months later, when the patient succumbed to miliary tuberculosis. The clinical picture and the microscope confirmed the diagnosis of lymphoma malignum, although the swollen glands became reduced in size under energetic arsenic treatment. Several writers have reported the coincidence of lymphoma malignum and tuberculosis.

41. Hereditary Relations Between Tuberculosis and Cancer.—Aronsohn has been investigating the heredity of his tuberculous patients, and has been much impressed with the fact that in the majority of cases in which no tuberculous hereditary antecedents could be discovered, one of the parents had had a cancerous affection. He describes the particulars of 20 such cases, and adds one in which a carcinoma of the throat occurred in a patient in whose heredity neither tuberculosis nor cancer could be traced, but the patient's two wives had both been tuberculous. He believes that conjugal tuberculosis usually affects the throat. The connection between lupus and carcinoma has been recently emphasized by Ashihara, who collected 126 cases of carcinoma developing on lupus, with 3 personally observed at the Breslau clinic. Lupus, Aronsohn suggests, may be to a certain extent the connecting link between cancer and tuberculosis. A lupous infiltration is one form of tuberculosis, and at the same time it may become transformed into a cancerous growth under certain unknown conditions. In this connection he cites Williams' observation that cancerous tumors disappear in the course of acute phthisis, while, on the other hand, carcinoma may begin as tuberculosis ceases. He found fresh tubercular lesions only once at the autopsies of 136 carcinoma subjects, while in 12 per cent. old tubercular foci were conspicuous. Megay has published a case of acute miliary carcinosis, terminating fatally in ten days, which resembled in many respects acute miliary tuberculosis. A number of cases have been reported in which carcinoma developed on the basis of a tuberculous lesion in the intestine or esophagus. Statistics indicate that there is heredity of cancer in about 10 per cent. of all cases, and Aronsohn observed tuberculous offspring from cancerous parents, in the same proportion. Jacobash noted cancer in the parents in 6 per cent. of 1500 tuberculous patients, and Riffel found 19 such cases in 46 families. The question as to the frequency of cancer in the children of tuberculous parents is still unstudied. Arguments in favor of the inherited character of the tendency to tuberculosis or cancer are the tubercular cerebral lesions found in very young children, also the fungous tubercular processes in children with no process in the lungs, while, on the other hand, persons with pulmonary affections seldom have these or any tuberculous bone or joint lesion. Billroth pointed out that persons with joint and bone affections usually die from exhaustion, and no tuberculous lesions are found in the internal

organs, but merely extensive amyloid degeneration. These autopsy findings are explainable by the assumption of congenital infection and not otherwise. If it should be proved that cancerous parents beget tuberculous children, then there is not only the inheritance of a predisposition to the reception of microbes, but every probability that direct congenital infection has taken place, and that the parasite of one disease, inherited by the child, either creates some special predisposition for the other, or else becomes transformed so as to produce it. If so, then we must assume that the phthisic diathesis may be inherited not only from phthisic, but also from cancerous parents, and that carcinoma, lupus and tuberculosis belong etiologically to the same family.

44. Treatment of Empyema.—Israel makes a vertical branch to the usual transverse incision for evacuating empyema. This enables the empyema to be drained at the lowest point. There is no stagnation, and healing proceeded with remarkable rapidity in the ten cases thus treated. He carries the incision down to the eleventh rib, resecting a portion of the tenth. The annoying tendency to coughing is avoided. Hemorrhage is more readily controlled and the cavity can be irrigated more easily.

48. Communicability of Bovine Tuberculosis to Man.—In this address, which was the feature of the last day of the Tuberculosis Conference, Koch reviews the various cases of supposed transmission to man of bovine tuberculosis, and shows that none of them will bear criticism. He proclaims that no case can be accepted as evidence which has not been examined postmortem, with certainty of tuberculosis of the udders of the cow giving the milk, and with the history of other persons using the same milk, and exclusion of all other sources of infection. On the other hand, no cases can be accepted as contrary evidence without demonstration of udder tuberculosis, sufficiently prolonged observation of the persons and testimony, as to whether the milk was boiled before using. For the present he reiterates that the injurious influence on man of bovine tuberculosis milk and its products is not proven. He affirms that the principal, and possibly even the only, source of infection of man is a person with tuberculosis who, in consequence of the unfavorable environment or his disregard of the simplest rules for the prevention of the infection of others, may thus prove dangerous for those around him. Instead of wasting our efforts in the superfluous task of preventing infection from bovine tuberculosis, attention should be concentrated more than hitherto on the prevention of infection from man to man in the conditions mentioned. Koch referred to Baumgarten's inoculations of a number of cancer subjects with bovine tuberculosis as important evidence in favor of its non-communicability to man. Koch remarked in conclusion that it is more interesting to seek for infection than for cases of resistance to infection, but it is necessary to collect information in regard to cows with tuberculosis of the udders, trace the history of the persons who have used the milk, and follow them and learn whether they became affected with tuberculosis in a year or two, and what form it assumed.

53. Early Diagnosis of Icterus.—Bouma recommends testing the blood, serum and urine for icterus in suspicious cases, even when they do not show the presence of bile to the eye. This can readily be done with a modification of Hammarsten's reaction, which he describes.

57. Indications for Interruption of Pregnancy in Nephritis.—Hofmeier thinks that there should be no question of inducing premature delivery or abortion in acute nephritis, as there is a possibility of a favorable termination, and as the interruption of the pregnancy has no influence in preventing the threatening eclampsia. In the chronic form and in "pregnancy kidney," the pregnancy should be interrupted if, notwithstanding appropriate medication in the former case and dieting in the latter, the condition grows steadily worse.

58. Ibid. in Internal Diseases.—Schauta reviews the entire list of internal affections and proclaims the conclusions for each in turn as derived from his own experience and that of others in respect to the advisability of interrupting the preg-

nancy. In case of pulmonary tuberculosis or mitral stenosis, he would not advocate interfering with the pregnancy except under certain conditions, while certain other affections are an absolute contraindication to it. The latter include the psychoses, pneumonia, pleuritis, pneumothorax, the acute infectious diseases, measles, scarlet fever, variola, erysipelas, diphtheria, dysentery, and the genital tumors, myomata, cysts, carcinoma. In cases of serious polyneuritis, tetany, nephritis and hyperemesis, the chances are that the child is doomed under any circumstances, while the mother may recover if delivered from the stress of pregnancy. In other affections, such as the chorea of pregnancy, etc., the child may be saved by premature delivery, and is in danger without it. In inevitably fatal cases of cerebral tumors or hemorrhage, miliary tuberculosis or pernicious anemia, it may be the only means to deliver the child alive. The child should be delivered in case of nephritis so soon as it is viable, or severe general disturbances are liable to follow. In the interest of the child accouchement forcé gives better results in moribunda than Cesarean section. The amaurosis of pregnancy requires energetic treatment and retinitis, immediate premature delivery.

59. Hysterectomy in Puerperal Infections.—Fehling agrees with the majority that hysterectomy is indicated in puerperal infection only when the latter is restricted exclusively to the uterus. In exceptional cases of puerperal uterine metrophlebitis (pyemia), hysterectomy may prove useful combined with ligation and extirpation of the thrombosed veins in the broad ligaments and of the spermatica or of the latter alone.

60. Ibid.—Leopold's address was reviewed in *THE JOURNAL* of December 6, p. 1491.

61. Tuberculosis of Female Sexual Organs and Peritoneum.—Veit summarizes his address delivered at the recent International Congress of Gynecology in the statements that peritoneal tuberculosis is always secondary, but the genital may be either primary or secondary, or merely a tubercular lesion in the peritoneal investment of the genitalia. Peritonitis with nodules, not referable to an ovarian tumor or carcinoma, is generally tuberculous. Peritoneal tuberculosis may exceptionally retrogress spontaneously, but can always be benefited by a laparotomy. The few cases of failure to cure that have been recorded were generally those with advanced tuberculosis in other organs. Recent cases should, therefore, be operated on without delay as soon as the affection causes trouble, and the intervention should be repeated if necessary. Chronic cases should be kept under supervision, and if there is no tendency to spontaneous retrogression, should be operated on. The intervention should be simply a laparotomy in the linea alba, complete evacuation of fluid and closure of the abdomen. If at the same time a completely isolated genital tuberculous lesion is discovered, the intervention should conclude with the radical operation. Veit is inclined to attribute the favorable result of the intervention to the influence of the serum, normal or with acquired antitoxic power. Three-fourths of all cases on record have been cured locally by the laparotomy, but tuberculous lesions elsewhere are not affected by it.

62. Ibid.—Martin is convinced that genital tuberculosis is much more common among women than is generally accepted. There are no pathognomonic symptoms of it, but inflammatory processes in the genitalia with tubercular lesions elsewhere should arouse suspicion. Chronic inflammatory processes evidently create a predisposition to it, as also dystrophy and hypoplasia. He believes that the infection is generally derived from the intestines, by way of the glands or peritoneum, or possibly through the blood. Several near points are usually affected at the same time, with sound intervals between them. The primary lesion may heal while the secondary infection continues a progressive course.

63. Ibid.—Amann attributes the source of genital tuberculosis in the female to primarily affected bronchial glands as the only origin thus far positively established by anatomic research. The lung or bronchial tubes are almost invariably simultaneously involved. Women are affected with genital tuberculosis in 20 per cent. and men in 3 per cent. of all cases.

Hypoplasia of the genital organs enhances the predisposition to tubercular lesions, also chronic inflammatory processes and the puerperal state. The tube is almost invariably the site of the first lesion. He thinks that primary infection from without of the female genitalia is extremely doubtful. No findings should be considered in the study of the subject except those of autopsies in which careful search has been made for hidden foci. There are many chances for infection by way of the air-passages in living with a tuberculous husband. Some of the most prominent pathologic anatomists affirm that they have never encountered an undoubted case of primary genital tuberculosis in the female adult. A primary tubercular lesion on the external genitalia or vagina has never been observed to date. Tuberculosis of the urinary passages is always descending. The kidney is first affected by way of the blood.

64. **Surgical Treatment of Uterine Carcinoma.**—Wertheim's address was reviewed in *THE JOURNAL* of December 6, p. 1491.

70. **Cryoscopy in Diagnosis of Death from Drowning.**—It is a well-established fact that in drowning the water drawn into the lungs finds its way into the capillaries and thus into the blood, diluting it to a notable extent. Carrara last year called attention to the difference in the concentration of the blood in the left heart, thus diluted in such cases, and in the right heart, which does not have time to feel the effect of this dilution. By determining the freezing point of the contents of the halves of the heart separately, a marked difference between the two halves is evidence that the subject died from drowning, as he has been unable to discover any other pathologic condition in which similar conditions prevail. Carrara's research was mainly on dogs, but Revenstorff has found in his experience at the Harbor Hospital at Hamburg that his conclusions are equally true in regard to human beings. In 5 out of 12 cases of drowning the difference between the freezing point of the blood in the left heart and the right was as .48 to .68; .28 to .55, etc. In the other cadavers the difference was merely .62 to .67; .77 to .81, etc. The negative result of the test, therefore, does not exclude drowning, but the positive result is absolute proof of it, and is a valuable aid in forensic cases, even for newborn infants. In none of his cases in which the test was positive could the slightest dilution be determined in the right heart. The difference between the two hearts ranged from .10 to .27 of a degree. The diagnosis is possible by this means in certain cases from mere inspection of the cadaver, before the autopsy. Advanced putrefaction will detract from its reliability as the freezing point of the blood in the right heart falls more rapidly than that of the left. [The figures refer to the Centigrade thermometer.—Ed.]

78. **The So-Called Hardening of Children.**—Hecker says that the cold bathing and sleeping in cold rooms which are applied so vigorously by many families as a means of hardening their children, have in reality the opposite effect in many cases. Their physicians are like the fishermen in the fairy tale who were terrified at the sight of the genii they had invoked. He has been examining 34 children brought up on these principles and finds that the systematic hardening process very frequently entails an exaggerated tendency to colds, sore throat, and respiratory affections, also to severe anemia and general nervous disturbances, neurasthenia, loss of appetite, restless sleep and irritability, with change of character. It may also induce acute and chronic recurring intestinal affections, and aggravate the course of infectious diseases, especially of whooping cough. He reports a number of cases in detail to sustain these assertions. Infants should always be kept warm at all times, he says, but after a child is a year old the hardening measures may be commenced, though very gently and gradually and strictly individualized. No furs should be worn, and the throat should not be wrapped up. During north-east winds, extreme cold and snowstorms, children should be kept indoors. The windows of rooms where young children sleep should not be kept wide open except in summer, and in a mild climate. If the child shrinks from a cold sponge bath, it should be applied very cautiously, and even pleasure in the bath is not an absolute criterion that it may not have in-

jurious after-effects. Cold sponging is better than cold douches for children, and once a day is enough. Cold water should not be used for children without a preceding medical examination, especially if they are nervous or anemic.

79. **Cinnamic Acid in Tuberculosis.**—Riegner has treated 9 cases of tuberculosis with cinnamic acid according to Landrèr's directions, and has observed 12 others treated by a colleague. The results by the intravenous route were very good and encourage further treatment. Intramuscular injections failed to disclose any beneficial effect. He thinks that suggestion has something to do with the results, but only as a subordinate factor.

80. **Gonorrheal Urethritis in Boys.**—Fischer adds 2 to the 69 cases on record. The course of the infection seems to be more rapidly acute than in adults, and the posterior portion of the urethra is soon involved. Strictures are not infrequent. The infection was extragenital in about two-thirds of the cases. Boys of about 6 were in the majority.

85. **Serum Treatment of Articular Rheumatism at Senator's Clinic.**—Menzer reports treatment of 33 patients with a serum made by inoculating animals with streptococci derived from the tonsils of patients with articular rheumatism. They were usually found unassociated with other bacteria. He is convinced that the bacteria in the nasopharynx may acquire such virulence under certain circumstances that they are able to overcome the resistance of the lymphatic apparatus in the throat, and penetrate into the blood. Here they induce metastatic affections at the points which are anatomically less capable of resistance, as consisting merely of fibrous tissue, with few cells. The joints, serous membranes and endocardium are prominent examples of this poverty in cells, and these are the points most frequently assailed. The reaction of the organism is manifested by local hyperemia, swelling and pain. The infection does not jump from joint to joint, but the reaction occurs wherever the bacteria encounter feebleness and gain a foothold. The new serum is not an antitoxin, but acts by re-enforcing the organism in its struggle against the infection. As the reaction is thus re-enforced the temperature rises and the affected parts become more swollen and painful, but this intensified reaction is brief, and soon conquers the invading streptococci and the patient is cured. It was impossible to immunize animals by means of the serum, as owing to the lack of previous passage of the streptococci through animals they were not virulent enough for this. Menzer proclaims that the results of the serum treatment in 33 cases in which it was applied have been extremely encouraging, and he recommends it for general adoption, although he disclaims the idea that he has found a panacea. In 7 acute cases treated with the serum alone, the joint affection and fever lasted on an average seven and seven and a half days. The patients were allowed to get up the seventeenth day, eight days after all pain and fever had subsided. The heart was clinically normal in all but one case, in which there was a slight systolic murmur. In 4 other acute cases, treated previously with the salicylates without effect, the joint affection and temperature lasted six and six and a half days. The heart was clinically normal when dismissed in 2 cases as also in a fifth case treated at home for eight days with aspirin before serum treatment was instituted. All the above cases convalesced rapidly without relapse. The majority of the joints could be used without pain by the third to fourth day. The fever keeps up longer, and he considers this an advantage over salicylic medication. The latter acts by reducing the reaction on the part of the organism instead of enhancing it like the serum. With salicylic medication the infection is not conquered, and relapses and exacerbations are liable to occur, while under this serum treatment there were no relapses nor exacerbations in any instance after the fever had once declined. Three of the cases were treated at Leyden's clinic.

87. **Levulosuria and Levulosemia.**—Rosin and Laband remark that spontaneous levulosuria may occur with little if any glycosuria, as in a case described. It may also occur in the course of diabetes mellitus, with a considerable amount of

levulose in the circulation, enough to induce rotation to the left. There may also be a large proportion in the urine, but not quite enough to change the rotation. They add that Seliwanoff's reaction is extremely valuable for the study of anomalies in the carbohydrate metabolism. This reaction is the bright red tint that develops when urine is heated with equal parts of fuming hydrochloric acid and a few grains of resorcin. In the case reported it was impossible to influence the levulose in an alimentary way.

94. Congenital Dislocation of Hip.—Heusner remarks that Lorenz, in 450 reductions of congenital luxation of the hip, has a record of 11 fractures of the neck of the femur, 1 of the pubis, 1 of the ilium, 3 transient paralyses of the perineus nerve and 5 of the crural, with 3 permanent paralyses of the sciatic nerve and one case of gangrene of the leg in a girl of 13, probably due to the unduly tight cast. In several cases Narath's hernia was observed and frequently there has been stiffness from imperfect fitting of the parts of the joint. In only two of the latter cases have there been permanent disturbances. Heusner and Hoffa have not been so fortunate in this respect. The acetabulum can not become shaped to hold the head in the few months of treatment. Altering the shape of the acetabulum is, therefore, not the aim to be striven for, but merely the shriveling of the capsule and musculature to induce the most favorable position for retention. It is, therefore, better to renounce the attempt to secure functional weight-bearing in cases which display a tendency to recurrence of the dislocation. The head is liable to be forced out of its cavity, instead of being pushed into it, if the patient be allowed to use the limb. Ducroquet of Paris has secured better results from the Lorenz method than Lorenz himself, Heusner asserts, as he does not allow his patients to be up and about. The chief merit of Lorenz's method is the extreme abduction which counteracts the injurious influence of the shortened adductors, and the head is brought to the front of the pelvis. But his method does not pay sufficient attention to the anteversion position of the neck and the stretching of the shortened abductors. The tendency of the foot to abduction is the result of the insufficient stretching of these abductor muscles, especially of the *gluteus maximus*, by this method. The thigh must be held in inward rotation to the utmost possible extent, in order to stretch these muscles. This requires a cast extending below the knee and even including the foot, in order to use the leg as a rotating lever, but Lorenz disregards this point and ends the cast above the knee in order to allow the child to be up and about. He is skeptical as to the necessity of this inward rotation which Lange, Hoffa, Schede and Heusner himself consider so necessary. The danger of redislocation is that of outward rotation, and Schede has inaugurated the latest phase in the treatment of congenital dislocation of the hip joint, by working against this tendency. He uses an extension apparatus, stretching both the sound and the affected leg, with counter-pressure at the perineum with a padded leather band. The legs are drawn far apart and the head of the femur is gradually pulled down on a level with the acetabulum. It is then slowly rotated inward, with strong pressure from behind against the trochanter with the fist, when the head can be heard grinding into its proper place. The Lorenz method of manipulating the capsule is then followed, on an ordinary table, and his cast applied with an abduction splint and leather pelvis girdle later or in case of bilateral luxation, a leather contrivance like swimming trunks, with a screw to exert pressure against the trochanters. Heusner does not agree with Lorenz that it is better to wait until a child is two years old before attempting intervention. He thinks that early infancy, with its energetic growth, offers the best prospects for regeneration, while delay invites rapid aggravation of the deformity. He illustrates the various devices that have been found most useful by himself and others.

109. Functional Improvement of Defective Hip-Joints.—Lorenz does not refer to any special affection, but to the various pathologic conditions of the joint from different causes in which the function of the joint is seriously compromised with pain when weight is borne on it. He has been strikingly

successful in such cases, he states, by a method of over-correction, securing an ultra-physiologic position of the joint, in cases of irreducible congenital luxations and in luxation fractures of the neck of the femur. The results attained encourage him to extend the scope of the intervention to healed coxitis with imperfect acetabulum formation and adduction contracture, also to arthritis deformans coxae. The aim is to induce a habitual ultra-physiologic over-corrected abduction. This abduction is carried beyond the physiologic limits of the excursion of the joint and is combined with ultra-extension. This combined position has never yet been applied in the treatment of the above categories of defective hip-joints. The upper end of the femur is transposed forward while the limb is placed in ultra-abduction. The maneuvers are accomplished without force. He commences with modeling redressement in order to widen the sphere of abduction. The contraction of the adductors is gradually overcome by blunt, bloodless efforts. Subcutaneous tenotomy is rarely required. By sawing with the ulnar border of the hand it is possible to carry abduction almost to a right angle. Manual rhythmic tractions are the next step. The extension screw is scarcely used at all now. Extension by two assistants, one pulling on a towel wound around the ankle, supplements the pressure of the operator from above on the trochanter, and is usually amply sufficient to mobilize the upper end of the femur vertically and gain 2 or 3 cm. in length. The joint is then over-stretched, aided by elevation of the pelvis, maximal flexion of the other leg and a weight of 20 to 25 kg. If the soft parts will not yield it is necessary to do at once a subcutaneous fasciotomy. The resistance of the subspinal soft parts can seldom be overcome without this. The result gradually attained is that the front surface of the thigh is far behind the frontal plane, and the joint is thus in ultra-physiologic over-extension. When this has been accomplished the head of the femur is mobilized. The neck may be fractured during these maneuvers, but the bone does not separate, and the head can be brought into place just the same. The intervention concludes with the final transposition of the mobilized head forward near the *spina ant. sup.* This is accomplished without further resistance by extreme over-extension combined with a degree of abduction in which the previous shortening becomes over-corrected. This position of the thigh, which is not so extreme as is required for retention of an actual reposition, is maintained by a cast enclosing pelvis and thigh to the knee. The patient is enabled to walk by raising the sole of the sound foot. After three or four months he corrects the abduction nearly to a parallel position of the legs, without ever quite reaching it. The over-extension is rigorously maintained. This new position is immobilized for three or four months. The patient is then able to walk without pain or trouble and with remarkable freedom from disturbances of any kind in comparison to his previous condition. The after-treatment consists in active and passive exercises in over-extension and abduction to maintain the habitual abducted position and prevent the head from resuming its previous backward dislocation. The patient should be able to raise the limb almost to a right angle when lying on his side, and carry it back far behind the frontal plane, to demonstrate the over-extension that is possible with the nearthrosis. The results have been highly satisfactory in all cases. The patients are able to walk without disturbances and limp much less. The limb was lengthened by 1 or 2 cm. One or two years are required to ensure the function of a nearthrosis.

110. Permanent Results of Forcible Reduction of Spondylitic Hump.—Vulpis exhibited two patients in 1898 whom he had straightened by forcible reduction of the hump according to Calot's method. Five years have now elapsed, and he gives photographs of both, which show that the perfect results attained have been permanent. The spine is straight, although possibly a trifle shorter than normal. Joseph has explained how this can occur in such cases by the wedging into each other of the diseased vertebrae. The hump was reduced in horizontal extension, the processes of four vertebrae were resected and a cast applied to the trunk from the back of the head to the knee or thigh. One patient was 5 and the other 8 years

old at the time. In both cases there was a large abscess in the abdomen.

The Public Service.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Nov. 27, 1902:

Assistant Surgeon-General J. H. White, to proceed to Key West, Fla., for special temporary duty.

Surgeon R. D. Murray, granted leave of absence for seven days from December 7.

Surgeon John Godfrey, granted extension of leave of absence for three months from December 13.

Asst.-Surgeon Carl Ramus, granted leave of absence for one month from December 1.

Asst.-Surgeon C. E. D. Lord, granted extension of leave of absence for one month from December 6.

Asst.-Surgeon C. W. Wille, on being relieved from duty at Cape Charles Quarantine, to proceed to Washington, D. C., and report to the director of the Hygienic Laboratory.

Asst.-Surgeon J. S. Boggess, relieved from duty at Reedy Island Quarantine, and directed to proceed to Cape Charles Quarantine and assume command of the service, relieving Asst.-Surgeon C. W. Wille, to proceed to Norfolk, Va., as recorder of board for physical examination of Senior Pharmacists F. L. Brown and F. S. Goodman.

Asst.-Surgeon C. C. Pierce, detailed to represent the service at meeting of the American Public Health Association at New Orleans, December 8-13.

Asst.-Surgeon W. C. Rucker, bureau letter of Nov. 19, 1902, directing him to proceed to Reedy Island Quarantine revoked, and directed to proceed to New York, and report to Surgeon G. W. Stoner, Immigration Depot, for temporary duty.

Asst.-Surgeon A. D. Foster, to proceed to Wilmington, N. C., and assume temporary command of the service during the absence, on leave, of Surgeon John Godfrey.

Asst.-Surgeon H. McG. Robertson, to proceed to Chicago, and report to medical officer in command for duty and assignment to quarters.

A. A. Surgeon B. W. Goldsborough, leave of absence granted for twenty-one days by Department letter of October 4, amended so that it shall be for one day. Granted leave of absence for three weeks from November 20.

A. A. Surgeon E. B. Hallett, granted leave of absence for three days from November 26.

Senior Pharmacist A. M. Roehrig, to report to chairman of board of examiners at Stapleton, N. Y., for physical examination to determine his fitness for promotion to the grade of pharmacist of the first class.

The following senior pharmacists are ordered—as Pharmacist Roehrig above—to report, for physical examination for promotion, to the chairman of the boards of examiners in the respective cities named:

John Achenbach, to report at Port Townsend Quarantine, Wash.
G. H. Brock, to report at Detroit, Mich.
E. S. Maguire, to report at Fort Stanton, N. M.
R. H. Gibson, to report at Gulf Quarantine Station.
T. V. O'Gorman, to report at New Orleans.
F. L. Brown, to proceed to Norfolk, Va., and report.
F. S. Goodman, same as Pharmacist Brown above.
Charles Miller, to proceed to Mobile, Ala., and report.
C. H. Woods, to report at Chicago.
F. R. Hanrath, to report at Cleveland, Ohio.
S. W. Richardson, to report at St. Louis.
J. V. LaGrange, to report at Chelsea, Mass.

BOARDS CONVENED.

Board convened at Washington, D. C., November 24, for the physical examination of Mr. G. M. Kohler and certain officers of the Revenue Cutter Service. Detail for the Board: Assistant Surgeon-General W. J. Pettus, chairman; Asst.-Surgeon J. F. Anderson, recorder.

Boards convened to make physical examinations of senior pharmacists, in accordance with the provisions of Paragraph 62, Regulations, Public Health and Marine-Hospital Service, approved Nov. 21, 1902:

At Chelsea, Mass., November 27, for the physical examination of Senior Pharmacist J. V. LaGrange. Detail for the Board: Surgeon R. M. Woodward, chairman; Asst.-Surgeon W. K. Ward, recorder.

At Stapleton, N. Y., November 26, for the physical examination of Senior Pharmacist A. M. Roehrig. Detail for the Board: Surgeon Preston H. Bailhache, chairman; Asst.-Surgeon A. J. McLaughlin, recorder.

At Gulf Quarantine Station, November 27, for the physical examination of Senior Pharmacist R. H. Gibson. Detail for the Board: P. A. Surgeon S. B. Grubbs, chairman; A. A. Surgeon J. A. Moncure, recorder.

At Norfolk, Va., November 27, for the physical examination of Senior Pharmacists F. L. Brown and F. S. Goodman. Detail for the Board: Surgeon J. B. Stoner, chairman; Asst.-Surgeon J. S. Boggess, recorder.

At Chicago, November 27, for the physical examination of Senior Pharmacist C. H. Woods. Detail for the Board: Surgeon C. E. Banks, chairman; Asst.-Surgeon L. P. H. Bahremburg, recorder.

At St. Louis, November 28, for the physical examination of Senior Pharmacist S. W. Richardson. Detail for the Board: Surgeon J. M. Gassaway, chairman; A. A. Surgeon H. C. Wakefield, recorder.

At New Orleans, November 28, for the physical examination of Senior Pharmacist T. V. O'Gorman. Detail for the Board: P. A. Surgeon C. P. Wertenbaker, chairman; Asst.-Surgeon J. W. Schereschewsky, recorder.

At Cleveland, November 28, for the physical examination of Senior Pharmacist F. R. Hanrath. Detail for the Board: P. A. Surgeon H. W. Wickes, chairman; A. A. Surgeon D. P. Osborne, recorder.

At Detroit, November 28, for the physical examination of Senior

Pharmacist G. H. Brock. Detail for the Board: Surgeon H. W. Austin, chairman; A. A. Surgeon R. Granberry, recorder.
At Fort Stanton, N. M., December 1, for the physical examination of Senior Pharmacist E. S. Maguire. Detail for the Board: Surgeon P. M. Carrington, chairman; Asst.-Surgeon J. W. Trask, recorder.

At Port Townsend Quarantine, Washington, December 1, for the physical examination of Senior Pharmacist John Achenbach. Detail for the Board: Asst.-Surgeon M. H. Foster, chairman; Asst.-Surgeon D. E. Robinson, recorder.

At Mobile, Ala., December 1, for the physical examination of Senior Pharmacist Charles Miller. Detail for the Board: Surgeon W. P. McIntosh, chairman; A. A. Surgeon J. G. Thomas, Jr., recorder.

APPOINTMENTS.

Holcombe McGavock Robertson of Virginia, commissioned (recess) as assistant-surgeon, Nov. 17, 1902.

Albert Douglas Foster of Michigan, commissioned (recess) as assistant-surgeon, Nov. 17, 1902.

Navy Changes.

Changes in the Medical Corps of the Navy, for the week ended Dec. 6, 1902:

Medical Director R. C. Dean, retired, ordered to Washington, D. C., for duty as president of the Naval Examining Board.

Medical Inspector S. H. Dickson, detached from the Marine Barracks, Washington, D. C., and ordered to the *Iowa*, for duty as fleet surgeon, South Atlantic Station.

Medical Inspector M. H. Simons, detached from the *Iowa*, and ordered home and to wait orders.

Surgeon M. H. Crawford, resignation accepted, to take effect Nov. 28, 1902.

P. A. Surgeon M. S. Elliott, detached from the *New York*, and to temporary recruiting duty at Pueblo, Colo., and thence to the *New York*.

P. A. Surgeon J. C. Rosenbleuth, detached from the *Wilmington*, and ordered home.

Asst.-Surgeon H. A. Dunn, detached from Cavite Naval Station and ordered to the *Vicksburg*.

Asst.-Surgeon F. A. Asserson, detached from the *Kentucky* and ordered to the *Wilmington*.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General Public Health and Marine-Hospital Service, during the week ended Dec. 5, 1902:

SMALLPOX—UNITED STATES.

California: Los Angeles, Nov. 8-22, 3 cases.
Colorado: Denver, Nov. 15-22, 10 cases.
Florida: Jacksonville, Nov. 22-29, 1 case.
Georgia: Atlanta, Nov. 19-26, 7 cases.
Illinois: Chicago, Nov. 22-29, 1 case.
Indiana: Indianapolis, Nov. 22-29, 3 cases.
Kentucky: Covington, Nov. 1-29, 64 cases.
Louisiana: New Orleans, Nov. 24-29, 1 case.
Maine: Bangor, Nov. 22-29, 5 cases.
Maryland: Cumberland, Nov. 1-30, 1 case.
Massachusetts: Nov. 22-29, Boston, 11 cases, 9 deaths; Cambridge, 1 case; Chelsea, 1 case; Lawrence, 1 case; Marlboro, 2 cases; Newton, 2 cases; Quincy, 1 case; Taunton, 5 cases.
Michigan: Nov. 22-29, Grand Rapids, 11 cases; Detroit, 57 cases, 1 death.
Missouri: St. Louis, Nov. 23-30, 9 cases.
Nebraska: South Omaha, Nov. 23-30, 3 cases.
New Hampshire: Nashua, Nov. 22-29, 17 cases, 1 death.
New Jersey: Camden, Nov. 22-29, 1 case; Newark, Nov. 22-29, 1 case; Jersey City, Hudson County, Nov. 23-30, 1 case; Bayonne, Hudson County, Nov. 23-30, 1 case.
New York: Nov. 22-29, Binghamton, 2 cases; New York, 5 cases.
Ohio: Cincinnati, Nov. 21-28, 3 cases; Cleveland, Nov. 22-29, 15 cases, 5 deaths; Hamilton, Nov. 22-29, 1 case.
Pennsylvania: Nov. 22-29, Altoona, 1 case; Erie, 9 cases, McKeesport, 1 case; Philadelphia, 5 cases, 1 death; Pittsburgh, 35 cases, 10 deaths; 4 cases imported.
Rhode Island: Providence, Nov. 22-29, 1 death.
South Carolina: Charleston, Nov. 22-29, 2 cases.
South Dakota: Sioux Falls, Nov. 22-29, 2 cases.
Wisconsin: Milwaukee, Nov. 22-29, 9 cases.

SMALLPOX—FOREIGN.

Ecuador: Guayaquil, Nov. 8-15, 1 death.
Canada: Quebec, Nov. 22-29, 1 case.
France: Paris, Nov. 8-15, 1 death.
Great Britain: Nov. 8-15, Dundee, 2 deaths; London, 2 cases; Manchester, 2 cases.
Italy: Naples, Nov. 10-17, 1 case.

YELLOW FEVER.

Colombia: Panama, Nov. 18-24, 4 cases.
Ecuador: Guayaquil, Nov. 8-15, 4 deaths.
Mexico: Tampico, Nov. 15-22, 13 deaths; Vera Cruz, Nov. 15-22, 16 cases, 11 deaths.

CHOLERA—INSULAR.

Philippines: Cebu, Sept. 29-Oct. 14, 5 cases, 2 deaths; Manila, Oct. 12-18, 19 cases, 18 deaths; Provinces, Oct. 12-18, 3,703 cases, 2,563 deaths.

CHOLERA—FOREIGN.

China: Hongkong, Oct. 21-28, 1 case, 1 death.
Egypt: Alexandria, Nov. 1-8, 1 case, 1 death.
Turkey: Gaza, Oct. 25-Nov. 1, 449 cases; Lydda, Oct. 25-Nov. 1, 75 cases; Jaffa, Oct. 25-Nov. 1, 5 cases.

PLAGUE—FOREIGN.

Africa: Cape Colony, Port Elizabeth, Sept. 25, 1 case, 1 death.
China: Hongkong, Oct. 21-28, 1 case, 1 death.
Egypt: Alexandria, Nov. 1-8, 1 death.
Japan: Yokohama, Oct. 19-Nov. 1, 2 cases.

OBSTETRICS AND THE GENERAL PRACTITIONER.*

M. HOWARD FUSSELL, M.D.

PHILADELPHIA.

My excuse for reading a paper with this title before the Section on Practice of Medicine is that I desire to bring before you the practice of obstetrics as it appears to the general practitioner, and while I have nothing new to suggest, I wish to impress the absolute necessity and practicability of the observance of rules by the general practitioner which have been formulated by specialists in the practice of obstetrics.

I believe it is too much the habit of men who see much of midwifery in general practice to believe and no practice, if not to say, that the strict rules which are now observed in hospitals the world over, and which are taught by all obstetricians, are at least unnecessary in general practice far away from closely populated centers. If this feeling is current, as I believe it is, it is my desire to so place it before this Section that we may all endeavor to do our best to follow what has now been proven to be absolutely necessary for safe practice. To the general practitioner belongs the arduous labor and the honor of conducting the vast majority of all maternity cases which occur. Lying-in charities and maternity wards of general hospitals care well for many of the poor; a few wealthy individuals have the great privilege of employing men who are especially trained in the work of obstetrics to care for their wives during the entire period of pregnancy, but the vast majority of maternity cases come under the care of the family physician. This is my excuse, as I have before said, for presenting this paper to this Section, for I take it that more general practitioners are connected with this Section than with any other of our Association.

Since Lister formulated the law of asepsis, maternity work in the hospitals has become an entirely different practice from what it was in previous years. Formerly mortality in the maternity wards of hospitals was extremely high; at present, both mother and child are perhaps safer in the wards of hospitals than in any other place. It is very questionable, although difficult to prove, whether there has been a corresponding reduction in the mortality rate in private obstetric practice. As general practitioners, as men to whom the majority of women trust their lives during the lying-in period, as individuals who have charge of the majority of the new-

born, it is our duty and our privilege to emulate hospital practitioners and make private obstetric work without avoidable mortality.

One of the most important duties of the general practitioner is to educate his *clientele* to understand that the physician who is to attend a woman in labor should be made aware of the pregnancy soon after it occurs; that they be made to expect that the doctor will have a constant oversight of the patient from that time until the end of the puerperium.

Too often, indeed usually, among the poorer classes, the doctor is not made aware of the expected labor until immediately before its occurrence, and then only because they feel that an unexpected call may not be responded to.

Among the duties of the physician before labor are the following: 1, Repeated urine examination; 2, regulation of the daily life; 3, attention to the breasts; 4, abdominal examination; 5, measuring of the pelvis in primipara; 6, instructions to the woman as to preparation for the lying-in period.

EXAMINATION OF THE URINE.

This is constantly neglected, much to the detriment of many patients. Its neglect often causes the sacrifice of their lives, and I thoroughly believe that if a pregnant woman of whose condition we have been informed and whose urine we have not examined for albumin, is seized with a puerperal convulsion, that we are certainly morally responsible for that convulsion. Indeed, I believe that failure to periodically examine the urine of every pregnant woman whom we are engaged to attend in labor is a criminal neglect. Every woman who is pregnant should have a monthly examination of her urine for albumin and sugar, and during the last two months an examination should be made every two weeks or every week, preferably the latter.

It seems to me that the general practice is for the physician never to examine the urine unless the woman gives some symptom of renal involvement. Nothing can be further from the standard of good practice. We all know that the vast majority of women who have convulsions in pregnancy have had a previous albuminuria which should have been discovered. We also know that the condition constantly gives no symptom (except the albuminuria) before the convulsion. Personally, I am not guiltless of blunders, but, as Le Conte has remarked,¹ "it is more profitable to profit by some other person's blunder than from one's own"; therefore, this case is quoted:

CASE 1.—About four years ago a lady called to engage me to attend her daughter, pregnant with her first child, who expected to be confined in one month. She stated that the

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee; Drs. Frank A. Jones, George Dock and J. M. Anders.

1. American Jour. of Med. Sc., December, 1901.

reaction she called was so that I would be sure to respond to the call when it came. She reported that her daughter was perfectly well, able to be about, without pain or ache. She was told to send the next day a sample of her daughter's urine. Early the next morning, about twelve hours after the lady was in my office, I received a hurry call to go and see the patient. I found her writhing in a puerperal convulsion. Her life was happily saved, but only at the expense of fearful suffering, both on her own part and on that of her relatives. In all probability these trials could have been averted if she had made her condition known early in pregnancy.

Such cases as the above could be repeated from my experience and, I fear, from the experience of all of you until you would tire of the hearing. Unfortunately the ending of many, many cases is death and not recovery.

It is not my purpose, nor will time permit me, to go into the treatment of puerperal eclampsia; the point which I wish to make—the point on which I most insist—is that the monthly specimen of the urine of every pregnant woman should be examined in a routine manner. It makes no difference whether she has symptoms or whether she has no symptoms. It is true that the vast majority of examinations so made will be negative, and the woman would have gone to a successful labor whether the urine had been examined or not, but one case of albuminuria discovered in time to prevent convulsions and death is certainly a recompense for many hundreds of cases examined where the find is negative.

I have suggested that the urine should be examined during the last two months every week or every two weeks; this is important. I have seen a fatal convulsion occur in the person of a woman whose urine was entirely free from albumin ten days before its occurrence. The first indication in this case was extreme headache, followed in a very short period by a severe convulsion, ending in death. Just ten days before this headache the urine was found to be entirely normal; at the time of the headache it was loaded with albumin.

REGULATION OF THE DAILY LIFE.

Unquestionably the majority of women who suffer seriously from morning sickness, from severe pain in any portion of the body, from annoying symptoms, without being told to do so, ask the physician's advice. But, unless some such symptoms do occur it is pretty certain that the average woman will not appear to the physician until the time of labor occurs. She should be taught that an occasional visit to the physician is necessary, in order to see that her general strength is as it should be; that she is taking the proper sort of diet and the proper amount of exercise. Constantly women who are not forced to do their work allow themselves to become so sedentary in habit and remain so much in doors that they become weak, anemic and entirely unfit for the severe throes of labor. All these details can be attended to properly if the woman is made to understand that she must make regular visits to her physician.

ATTENTION TO THE BREASTS.

I believe that much distress can be avoided if regular attention is given the nipples before the labor begins, so that a retracted nipple may be made prominent and the skin over it in a proper condition to resist the maceration of suckling.

ABDOMINAL EXAMINATION AND MEASURING OF PELVIS IN PRIMIPARA.

I believe that during the seventh or eighth month of pregnancy it is wise, and indeed often imperative, that

an abdominal examination be made in order to know the presentation of the child. At the same time an examination of the pelvis should be made, without unnecessary exposure to the woman. The use of an ordinary Martin's pelvimeter is all that is necessary in order to assure us that our patient is not suffering from some deformity of the pelvis which will prevent the safe delivery of the child. The necessity of this procedure must certainly have presented itself to many of us who have much to do with maternity cases. Some which recently occurred in my own practice will suffice to show its advisability:

CASE 2.—Mrs. M. called on Dr. B. of my ward on the evening of April 1, 1902, to attend her in labor, never having spoken to him of the expected labor. He responded to the call and at once recognized that some serious trouble was at hand, and called me in to help. We discovered that so far as the external appearance of the abdomen was concerned it was a head presentation. Examination, however, at once revealed that it was a face jammed hard down into the pelvis, making it impossible to change it into a vertex. Examination of the pelvis showed the anterior posterior diameter very much reduced. A version was performed, the woman safely delivered, but at the expense of the life of the child. A previous measurement of the pelvis could have shown the deformity and made the physician watchful.

CASE 3.—Another case illustrates the value of a simple abdominal examination before labor begins. One of the members of this society was ill, and I was called to attend one of his patients in labor, who had never consulted him previously. The moment the abdomen was observed it was found that the child was not presenting by either pole, and the transverse diameter of the abdomen was greatly in excess of the normal. The head could be felt up above the rim of the pelvis, to the right. Examination discovered an arm protruding, the membranes of course ruptured; the woman much exhausted; the cord prolapsed; the child dead.

In this last case, unquestionably a previous examination of the abdomen would have shown that we had an abnormal presentation, and this could have been confirmed by a vaginal examination, which would have allowed the physician to have been in attendance in time to either correct the presentation or perform the version early, and probably have saved the child's life.

I am very well aware that both of these procedures are rarely practiced even by men skilled. I am equally sure, however, that if we gave the necessary time (and the time is not long) to make such examination we would be enabled to save life frequently and always save the family much distress.

INSTRUCTIONS TO THE WOMAN AS TO PREPARATION FOR THE LYING-IN PERIOD.

Unless the woman is instructed, she will either have nothing out or ready for her labor, or else is likely to have nothing which in these latter days seem necessities. She should be instructed to have her bed properly prepared, to have an abundance of clean water, clean towels, clean cloths, to have basins and soap. Attention to these slight details will certainly save us, as physicians, much annoyance and will expedite the labor and save us time.

MANAGEMENT DURING LABOR.

Another division of the care of obstetric cases is the management of a case during the labor itself. What I have said about the care of a case before labor begins I believe is correct. I am well aware, however, that the very great care which Nature gives to women allows the neglect of the duties of the physician which I have outlined to be fraught with relatively little harm, but

the neglect of our plain duty in the conducting of every case of labor in itself threatens the life of our patient.

If Godliness is ever second to any attribute, certainly it is second to cleanliness in the management of a labor case. The one thing that we want to remember always is that we must be absolutely clean, surgically clean, and we will have relatively little trouble with what are erroneously called malaria, milk fever and various other names which are only misnomers for sepsis. I have often wondered whether the use of antiseptic solutions is an unmixed good, so frequently have I seen gentlemen simply rinse their hands with soap and water, immerse them in antiseptic solution, and be fully convinced that their hands were aseptic, that I have often wished they knew nothing whatever of bichlorid of mercury and its like.

The man in general practice is constantly called in the middle of a busy day to attend a case of labor; he is hurried; he does not wish to remain if it is necessary; indeed, he can not do so, but he should never allow his hurry and his desire to get through to interfere with the first law of cleanliness.

My idea of the practitioner's duty under such circumstances is this: it is absolutely necessary, both for the safety of the woman and the child, and for the economy of the physician's time, that he should know exactly how far advanced labor is. It is true that by external manipulations one may discover fairly well the presentation of the child, and whether or not labor is in progress, but, to me at least, a vaginal examination is absolutely necessary to discover whether I must stay with my patient or whether I may safely leave her, and for how long.

The first thing that I do before making a vaginal examination is to take off my coat and waistcoat, roll up my sleeves above my elbows, scrub my hands and forearms thoroughly for five or ten minutes with brush, soap and water, clean my finger nails with a knife or nail cleaner, then immerse my hands in a strong bichlorid solution, 1-1000 or 1-500. Having done this I have the woman in a proper position for examination, and will allow nothing whatever to touch my hands; especially they must not be wiped off with a towel, but be taken dripping from the antiseptic solution and the examination immediately made.

Having made this examination I am in position to know the progress that labor has made. If it is safe for me to do so I leave the house, giving instructions what is to be done during my absence. If I must remain I immediately give my instructions. If the bowels have not been moved very recently they are ordered emptied by an enema; the exterior genitals are washed with clean boiled water. A vaginal injection is *not* to be given.

I then prepare myself for the labor by dressing myself in a clean duck coat and trousers. This I consider of a great deal of importance; in the first place it looks neat, in the second place it protects the clothing and allows one to go promptly from a labor case of severity to other cases without any trace of the labor. In the third place, and of the very greatest importance of all, it protects the woman against contamination from dusty, dirty clothing. Any physician who drives about all day is in no sense in a proper state of cleanliness to make it safe for him to bring his clothing in close contact with the woman in labor. It is very little trouble, practically no trouble, to carry in the obstetric bag a clean pair of trousers and a clean coat.

I then have placed on the bed a Kelly pad, which has been cleansed by the nurse in attendance. If we trust

to the persons about the house, and remember, I am speaking now of the ordinary every-day, common labor case to which the majority of us are called, we will be handed an old quilt; an *old* one, a piece of carpet, or anything that is thick, it makes no difference whether it is clean or not. The Kelly pad will last for years, is cleanly and will insure the woman not being poisoned from that source.

If the labor is a simple one, the presentation and position normal, there is very little else to be done except to leave the case to Nature. As few vaginal examinations should be made as is practicable, but previous to every examination, if the hands have been used for touching objects about the room, they should be again scrubbed, again immersed in antiseptic solution before the examination is made, and if this procedure is carefully carried out I really think that it makes little difference how many examinations are made; but, as I say, repeated examinations are useless, and by a possibility may be harmful and therefore should be limited.

I do not propose to at all discuss here when to use forceps. The subject would lead me entirely too far afield, but if forceps are to be used the following procedures are imperative: First, have the forceps carefully boiled in the receptacle on purpose for it, if there is one, if not, place the forceps in some vessel large enough to entirely cover them with water and allow them to boil for 10 or 15 minutes. Place the woman in position, carefully scrub the genitals, reprepare the hands by scrubbing, clean the finger nails, and lastly, but not most important, immerse them in antiseptic solution. Have the forceps brought to the room in the receptacle in which they were boiled. Do not allow them to be touched by any one, do not touch them with anything except a clean hand or a perfectly antiseptic cloth which has been boiled or immersed in solution; do not wipe the forceps off. I have seen a man carefully boil his forceps, just as carefully scrub his hands, take the forceps from the receptacle, deliberately pick a towel up from the floor and wipe off the forceps. Certainly all the precautions of boiling and of scrubbing the hands had been made useless by this act, which was entirely needless, needless even if a clean cloth had been used, but more than needless, harmful, when a soiled towel had been used. Let the forceps be applied and the child carefully delivered. If there is a tear let it be at once sewed with needle and silk or gut, which has been boiled with your forceps.

The pad which is to be applied to the vulva for cleanliness sake must also be absolutely clean. The monthly nurse who is so common in most houses will likely hand to you a bunch of rags which certainly look anything but clean, and which, nine times out of ten, have been lying on the floor in a closet. Of course, these must be discarded, and either a cloth which you know to be clean or one which you have yourself boiled used in its stead.

In a word, every time any object is to be brought in contact with the genitals of a lying-in woman that object, be it hand, forceps, needle or what not, must be as near aseptic as it can possibly be.

MANAGEMENT OF THE PUERPERIUM.

With the birth of the child, the severance of the cord and the application of the binder, it appears to be, in the minds of many practitioners, that their active duty ends. It seems to me that one of the most important points of labor is to see that the lying-in woman is perfectly cleansed after labor; unless there is a trained nurse in attendance this will be imperfectly done if

it is not personally attended to by the physician. One should not allow any false feeling of modesty to prevent him from making, first, an ocular inspection of the parts, to see that there is no tear, and if there is a tear in the perineum it should be immediately repaired, it makes no difference what its size. The parts should be most thoroughly cleansed and a perfectly clean cloth applied to the perineum for the purpose of protection.

I believe that no vaginal douche should be given after an ordinary case of labor. If it seems wise that such a douche should be administered, certainly it should not be entrusted to the hands of any but a skilled nurse. There still remains in the minds of many practitioners, I fear, the remembrance of the former idea that a vaginal douche be given after every labor. If this view is not held by the physicians it is certainly tenaciously fixed in the mind of every ordinary monthly nurse. Unless instructions be given to the contrary a nurse is pretty sure to give what she calls a cleansing wash. She will use without boiling any syringe that chances to be in the house; she will use unboiled water; she never dreams of washing her hands, and much more frequently does harm and threatens the life of her patient with this misnamed cleansing than she does good.

One of the most marked examples of the harm which can come from indiscriminate douching came to my notice during the past winter. I saw, with a fellow practitioner, one of the best examples of puerperal sepsis which has ever come to my notice. A woman was extremely ill with a septic pneumonia. She hovered between life and death for weeks. The labor had been one of the most rapid that could possibly be. The doctor was in attendance but a few minutes when labor was completed. Only one vaginal examination was made. On the third day there was a chill followed by fever, which lasted for weeks, eventuating in pneumonia. On questioning the nurse, she said: "Well, Doctor, the fever could not have come because the patient was not kept clean; I gave her a douche every day, and sometimes twice a day." On questioning it was discovered that neither the nozzle of the syringe, the syringe itself, nor the water had been boiled, and, of course, the nurse's hands had not been properly cleansed. There is not a particle of doubt in my mind that this woman's severe illness occurred because of the over-zealousness of her nurse. Now if such women are not given absolute instructions to keep their hands off the patient such procedures will constantly occur.

If a catheterization is necessary after labor it, of course, should be done either by a trained nurse or by the physician himself. This act, which is perfectly free from danger and easily done, may be fraught with fearful consequences if all the parts, the hands of the person catheterizing and the catheter itself are not cleansed. Only last week I was seeing, in consultation, a lady and advised that she be catheterized in order to obtain a specimen of urine. The physician removed from his pocket a silver catheter, black with age, and before I could interfere or know what he was going to do, he inserted this vilely dirty instrument into the bladder. It so happened that this case was in extremis, but it would have made no difference certainly to this physician whether a long life was expected or not, the same dirty catheter would have been used. This instance shows that the truth of these remarks are certainly yet to be received by certain practitioners. Every physician has now the opportunity of observing in hospital operating rooms what surgical cleanliness means. Let him avail himself of the opportunity.

I have tried to detail what can be briefly summed up as follows: Attention to the woman very early in pregnancy until the puerperal period is ended, before labor examination of her urine, regulation of her habits, knowledge of the size of the pelvis, knowledge of the presentation of the child, during and after labor surgical cleanliness, such cleanliness as can only be thoroughly learned by observation in the operating room of a hospital.

THREE CASES OF INVOLUNTARY MOVEMENTS IN LOCOMOTOR ATAXIA.*

J. H. W. RHEIN, M.D.

Assistant Physician to the Philadelphia Orthopaedic Hospital and Infirmary for Nervous Diseases; Neurologist to the St. Agnes Hospital; Physician to the Philadelphia Home for Incurables, Etc.
PHILADELPHIA.

The following cases illustrate three different forms of involuntary movements in locomotor ataxia, namely, choreiform movements; irregular, slow contractions of groups of muscles, and a fine rhythmical tremor. I have in a previous paper¹ classified the involuntary movements in tabes as follows: 1, Associated movements which may exist also in other forms of organic diseases of the nervous system; 2, sudden twitching of the trunk or extremities, occurring with or without pain and more frequently at night; 3, twitchings in isolated muscles or parts of muscles; 4, fibrillary twitchings; 5, rhythmical tremor resembling paralysis agitans; 6, passive movements, such as those which occur when a patient attempts to sit up in bed without the assistance of the hands or when he coughs; and finally, 7, involuntary movements previously described as athetoid movements. To this classification, I think, may be added choreiform movements. These, however, I believe to be rare. The case reported in this paper is the only one I have ever seen in my experience, which covers a great many cases of this disease.

CASE 1.—The patient was a widow, 66 years of age, who had always enjoyed good health. The family history was practically negative. Her father was killed; her mother died of apoplexy at 61 years of age, an only sister at 42 succumbed to Bright's disease. She had one child who died of "congestion of the liver" at ten years of age. Though she had always done her own housework, her life had not been especially hard save for one serious exception. Her husband died of insanity after three years' illness which was known only to the patient. There was no specific history, and the patient was always temperate in the use of alcohol.

Her present disease began in 1883, the first symptom being sharp, shooting pains in both legs and thighs. After a year her knees "gave way" and her gait grew more and more uncertain and unsteady until finally in 1893 she lost the power of walking entirely. Early in the disease, about a year after the pains first began, choreiform movements made their appearance in the arms, legs and body. These varied in severity from time to time and have persisted to the present. For five years she had noticed a failure in her sight, occasionally diplopia and a persistent ptosis of the right eyelid. Since 1893 there had been retention of urine and from time to time involuntary discharge if catheterization was neglected. The rectal sphincter had not suffered.

EXAMINATION.

On examining her April 28, 1902, for the first time, I found her greatly emaciated generally. There was also, however, evidence of atrophy affecting certain groups of muscles. Both

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Richard Dewey and H. A. Tomlinson.
1. Read before the Philadelphia Neurological Society in April, 1902.

anterior and posterior calf muscles on both sides were markedly wasted, while the anterior thigh muscles have practically disappeared. The posterior muscles were in a fair state of preservation. In the arms the biceps and deltoids were wasted to a degree, and the trunk muscles were profoundly involved. There was no hemiatrophy of the tongue. The knee-jerk, plantar reflex, Babinski reflex, bicep-jerk, chin-jerk and abdominal reflex were all absent and could not be developed by reinforcement. There was distinct and characteristic change in sensation. Pain sense was lost below the knee on both sides. Heat sense was impaired irregularly all over the body especially below the knees, left side of trunk and arms, while in the face and hands it was preserved perfectly. Deep pressure was felt poorly in the legs and she localized very poorly. On the plantar surface sensation was delayed three seconds. The results of the eye examination were as follows: Typical reflex iridoplegia was present. There was partial ptosis of the right eyelid, and the movements of the eyeballs were restricted in certain directions. The disc was pale grey and atrophic.

The feet were held in the position of talipes-equinovarus due to contraction of the posterior tibial group of muscles. There were no atrophic bone changes except in the index, middle and ring fingers of the right hand, where at the metacarpophalangeal articulations there were crepitus and some slight deformity. This followed an acute cellulitis, the result of some insignificant injury.

The symptom which makes this case unusual and worthy of being reported was the choreiform movements which the patient presented. The head, arms and body were in an almost constant state of movements resembling very closely those observed in Sydenham's type of chorea. They were greatly increased by emotional disturbances or voluntary muscular effort and during conversation. They ceased during repose to a great extent and entirely during sleep. There was observed in addition to this a slow involuntary clonic spasm of the fingers of both hands when the eyes were closed. Usually two or three fingers were moved, but one or all sometimes were involved.

CASE 2.—The second case presents a different but equally interesting form of involuntary movements. The patient, 55 years of age, a widow, gave the following history: Her father died of an unknown cause, probably not from a nervous disease; her mother of heart disease at 70; a brother of the same disease at 51; another brother of pneumonia; a sister in child-birth, and three other sisters of causes which were unknown. Two of her children died of cholera infantum and typhoid fever respectively. She never had a miscarriage. As a child, she suffered from scarlet fever and measles without sequelæ. She had always worked hard all her life at housework. In 1886 she suffered from an eruption which she described as being first like a flea bite, spreading to the size of a dime and extending all over the body. It lasted three or four weeks, and was not associated with sore throat or alopecia. But since then she has complained of pain in her legs from the knees down, of a shooting character. It was not until 1894 that the legs became unsteady, and thereafter the incoördination was progressive. A year later, upon turning away from her bed the tibia snapped three inches above the ankle-joint. Since then she has never walked, though the fracture healed promptly. In 1894 the left knee-joint began to swell and at the time of the fracture of the tibia was considerably swollen. It was only slightly painful then, and at no time since has she suffered except from the deformity. There has been a gradual change in the joint ever since, until at present there is an outward dislocation of the patella, an enlargement of the articulating surfaces of the bone and a marked disorganization of the joint. The bladder sphincter became incontinent about four years ago, and in the last two years there have been rare involuntary fecal discharges. She has had some transient diplopia in the last two years.

Examination.—Her condition upon examination in April, 1902, was as follows: There was great wasting of the thighs and legs, especially in the anterior tibial group. The arms and body were in a fair state of preservation. The left foot was

held in the position of equino-varus. Common sensation was present but delayed. Pain sense was retained. There was here and there some alteration of the heat sense, i. e., to cold there was a hyperesthesia everywhere, while hot objects were not felt at all on the legs. Heat sense in the hands was normal and sensation otherwise was unaffected in the arms and hands. She localized perfectly everywhere. The left leg was weak. In the right leg muscular power was fairly well retained. The grasp was good on both sides. The knee-jerks were absent and not reinforceable. The plantar reflexes were exaggerated and the Babinski reflex was present. Incoördination in the arms and legs was present, slight in the former, marked in the latter. The heart and lungs were practically normal. Argyll-Robertson pupil was present, the pupils were irregular in size, the left a trifle the larger. There was no change in the discs.

Thus far the symptoms I have related do not deviate from the usual picture of tabes. Let me now draw your attention to the special feature of the case. In the left leg a clonic contraction of the toes was observed which was almost constant. Sometimes the movements were slow, sometimes rapid, but always rhythmical. During sleep they ceased entirely. The patient was only conscious of the condition when her attention was called to it. All the toes were involved, but especially the first three.

CASE 3.—The third case was a man 57 years old, single, presenting the following history: All his family were long lived and were free from any pulmonary, malignant or nervous diseases. The patient stated that he had been always healthy, had never suffered from any serious illness, had been always temperate in the use of alcohol and had smoked excessively. He was infected in 1883 by syphilis, had a single lesion without secondary manifestations. About 1893 he began having the characteristic pains from which he suffered five years, when numbness of the hands, unsteadiness in walking and a fine tremor in both hands gradually developed. By degrees the ataxia increased until in February, 1898, he was unable to walk and has remained bed and chair fast ever since.

Examination.—I examined him for the first time in May, 1898, when I was struck at once by the curious tremor which he presented. The hands were the seat of a fine rhythmical tremor resembling in a striking manner that seen in Parkinson's disease. The pill rolling position of the fingers were typically illustrated. The tremor was still further like the latter disease in the manner to which it responded to voluntary effort. When the patient took a cup in his hand, the tremor was quieted for a few seconds only, after the expiration of this time to be increased. Rest quieted the tremor and muscular effort in one hand first quieted then increased the movements in the other. It was absent during sleep. There was no rigidity of the muscles nor any other signs of paralysis agitans. I therefore concluded that I was not confronted with a case of tabes complicated by paralysis agitans, but that the tremor was a symptom of the former disease. Besides this symptom there was present the usual picture of this disease, namely, characteristic sensory changes; incontinent urination, incoördination in the arms and legs, absence of sexual desire and lost knee-jerk.

The examination of the eye disclosed the presence of Argyll-Robertson pupil, grey discs and some refractive error. There was general emaciation but no localized atrophy. The heart and lungs were not conspicuously diseased, and the urine showed no abnormality.

334 S. Fifteenth Street.

DISCUSSION.

DR. H. N. MOYER, Chicago.—This symptom complex is exceptional. I do not recall a single case of tabes which resembled paralysis agitans, though occasional rhythmical tremors of single groups of muscles have been noted. I am not familiar with the type of cases which the Doctor has described. It is a matter of classification, and I am not sure that these cases ought to be included in tabes, not with my understanding of tabes. The first case described presented the ordinary symptoms of tabes, but there were other symptoms. I recall

a number of cases with mixed symptoms in which the diagnosis was kept in abeyance, in some of them for years, and which were ultimately labeled disseminated sclerosis. There is a mixed degeneration in these cases, and I am quite sure that there is a difference between these cases of disseminated sclerosis or mixed degeneration of the nervous system, and what I term cases of tabes. Of course, if we have a disseminated sclerosis in which the posterior columns are involved we get the ordinary symptoms of tabes, depending on its location, but it seems to me that these cases should not be labeled tabes. It is of little moment what term is used to designate them, the interesting thing is the association of the symptoms. I recall the case of a physician who was ataxic; but few who saw him could agree on the diagnosis. Tabes was suggested only to be rejected. It was several years after the first development of the condition before it finally impaired his usefulness and he became practically confined to the house. If you saw him now, you would quickly diagnose the disease as disseminated sclerosis, but in its early stages there were no distinguishing marks of the disease.

DR. D. R. BROWER, Chicago—I wonder whether Dr. Rhein had not in at least one of these cases a combination of degenerative diseases. There are some things in it that suggested Huntington's chorea. I do not see why tabes and Huntington's chorea could not be present in the same subject, as I don't think tabes gives exemption from anything. What brought that to my mind was that I have just gotten through with the treatment of a case of foot-drop and paralysis of the lower extremities. After some little study and examination the diagnosis was made of alcoholic neuritis, and after inquiring into the patient's case we found that he was an old tabetic; that he had had tabes for a number of years. At first glance the case was a typical one. This was an instance of tabes and alcoholic neuritis associated in the same person. He has now recovered from his alcoholic neuritis, but the original tabes remains about the same.

DR. J. D. MCCARTHY, Philadelphia—Any one who studies the pathology of tabes knows that there is a large percentage of tabetic cases in which the disease starts as tabes in the posterior routes and affects the posterior columns, in which later it is associated with a diffused sclerosis affecting the lateral columns. The reflexes, and especially the present Babinski reflex, point to involvement of the motor tracts. Disseminated sclerosis may begin in some cases in the posterior column and in those cases it will have ataxia as a symptom. Dr. Burr and myself reported two or three years ago to the American Neurological Association such a case. I think that case had been diagnosed by a very prominent neurologist as a case of locomotor ataxia, and the patient had never suffered from lancinating pain which occurs in tabes; the ataxia was such as you get from attacks of disseminated sclerosis in the posterior column. Another neurologist suggested sclerosis of the syphilitic type, but the true condition was entirely unsuspected at that time. The autopsy showed a typical case of multiple sclerosis. I think these cases are very numerous and that some of these cases of disseminated sclerosis beginning in the posterior column present nearly the same clinical picture as is presented in tabes. The case of Dr. Rhein's was evidently a case of probably the dorsal-cervical type of tabes in which the Babinski reflex was present and indicated involvement of the lateral columns. Too much stress is laid in diagnosis on these so-called cardinal symptoms. But the most of the cases of multiple sclerosis that we get in this country, and I have examined several cases microscopically in the course of the last three or four years, do not present all, and some of them none, of the so-called cardinal symptoms of multiple sclerosis. In Dr. Rhein's cases, I would like to know the condition of the tonus of the muscles; Von Bechterew decided a condition of hemic hypertonia, due to an irritative cerebral lesion, resulting in irregular movements.

DR. F. SAVARY PEARCE, Philadelphia—The choreiform movements which have been described as being present in these cases of Dr. Rhein's have appealed to me as probably being cerebral in origin whatever the pathologic condition in the cord may be, i. e., functional or organic disease. And it seems to me that

we are right in assuming that the choreiform movements are cerebral in origin since chorea is due to cerebral imitation, whether the disease be sclerotic or nutritional in character as regards the spinal cord.

DR. C. H. HUGHES, Cleveland—When Dr. Brower referred to the mental condition of these patients, the thought occurred to me in regard to this condition which is so common among the insane, and I thought the Doctor was going to touch on that. I think the effort to systematize sclerotic involvement of particular systems of the cerebrospinal axis is probably at fault in regard to these cases. Now it is not necessary for us to assume that when we once discover the route of a sclerosis that it is going to be a typical systematic involvement of the posterior columns alone. I have seen a great variety of cases, of course, in 40 years of observation, 30 years of which have been devoted exclusively to neurologic practice, and I have seen a number of cases, and made some mistakes. The symptom grouping to my mind establishes a primary condition of posterior sclerosis, and while I believe sclerosis is the primary involvement, I would not be disposed to restrict it to the posterior column. I think the sclerosis will extend into the anterolateral columns as well. I think when sclerosis is once established we may expect to find it in other regions as well as in the posterior column. The other signs are frequent pains, the Argyll-Robertson pupil, the cineture feeling and all the typical tabes dorsalis. But sometimes when we observe our cases over a series of years we find symptoms of cerebral sclerosis develop likewise. I have seen these cases last fourteen or fifteen years and then the sclerosis had become generally diffused throughout the near axis. I remember one case of a particular individual in my locality, where the trouble began with posterior sclerosis and where the individual had no tremor, which, of course, does not usually occur in posterior spinal sclerosis, yet he ultimately developed all the symptoms of disseminated sclerosis including intention tremor, and finally became mentally involved, but only during the last part of illness. He was a man of marked organic stamina, a farmer, who had contracted the condition by riding at night-time from the city, fourteen miles distant, to his farm, in order to avoid the heat of the day during the summer. And so the more I see of sclerosis the less inclined I am to restrict sclerosis appearing first as tabes dorsalis, to the posterior spinal columns and the posterior root zones of the cord; it may become disseminated.

DR. J. H. W. RHEIN, Philadelphia—My object in reading the histories of these cases was not so much to describe a new symptom or group of symptoms in locomotor ataxia, but to call attention to the fact that the present-day text-books neglect to describe these symptoms to the extent which they deserve. If I have given the impression that these are cases of disseminated sclerosis, then the fault is not with the cases, but in the manner of describing them, because if we will concentrate our minds on all the symptoms presented and the history of their development, we will recognize that they are not cases of disseminated sclerosis, but locomotor ataxia. The gradual progressive incoordination, characteristic pains, bone changes and ocular symptoms preclude any doubt in the diagnosis. In their present condition we might describe the patient as being in the paralytic stage of locomotor ataxia. They have not the mental changes, the characteristic tremor and the nystagmus of disseminated sclerosis. The fact must be noted that in one case the lateral columns appear involved, as indicated by the presence of the Babinski reflex. In the last stages of locomotor ataxia we not infrequently find postmortem that the disease has involved the lateral tracts.

Incompatibility of Protargol and Cocain Hydrochlorate.
—Von Astruc and Cambe are quoted (from the *Bulletin des Sciences Pharm.*) in a number of pharmaceutical journals as pointing out that the precipitate formed in the preparation of solutions of protargol and cocain hydrochlorate may be avoided by using a 1.5 per cent. solution of boric acid, as a solvent, instead of water. The precipitation is due to the slightly alkaline reaction of the protargol, which is counteracted by the use of boric acid.

SANITARY MEASURES FOR THE PREVENTION OF TUBERCULOSIS IN NEW YORK CITY AND THEIR RESULTS.*

HERMANN M. BIGGS, M.D.

Medical Officer, Department of Health; Professor of Therapeutics and Clinical Medicine, and Adjunct Professor of the Practice of Medicine, University and Bellevue Hospital Medical College; Visiting Physician, Bellevue and St. Vincent's Hospitals.

NEW YORK CITY.

There is no problem which confronts the sanitary authorities of the large municipalities at the present time exceeding in its importance and magnitude that presented by the tuberculous diseases, nor is there any other sanitary proposal which offers promise of such large returns in a diminishing morbidity and mortality rate as one which provides successful measures for the prevention of tuberculosis.

The problem is not a new one. The tuberculous diseases are not more prevalent than formerly; on the contrary, there has been a steady and very material decline in the death rate caused by them; but only in recent years have the sanitary authorities and the medical profession begun to partially realize the great possibilities in the restriction of this disease. A comprehension of the full meaning of the discovery of Koch on the prevention of tuberculosis has very slowly found its way into the minds of the medical profession, and even now, after twenty years, a large proportion of the profession have failed to grasp its vast significance. Statistics showing the great prevalence of this disease have been quoted so frequently as to have almost lost their meaning, and the people, the sanitary authorities and even the medical profession, have become indifferent to the vast expenditure in suffering and death unnecessarily paid to this evil. Only limited and ineffectual efforts are being made in its suppression. We still view with comparative indifference the ravages of a disease which causes from one-fourth to one-third of the suffering and death at the best period of life, and this, too, when the evidence at command should be, it seems to me, conclusive to every reasonable mind, that it can be mostly prevented at a comparatively small cost in sacrifice, labor and money. I make this statement with a full realization of its meaning, and after a familiarity with the sanitary problems involved, gained by an active participation in their study in a great city for a period of more than fifteen years.

A description of the methods now employed by the Department of Health of New York City for the prevention of pulmonary tuberculosis may properly be prefaced by a brief account of the inception and development of this work. In 1888 the sanitary importance of the tuberculous diseases was urged on the Board of Health of New York City by the writer, and in 1889, in response to a resolution of the board, a communication was made to the department by the writer and the associated consulting pathologists of the department, setting forth the essential facts regarding the nature of the disease, the usual methods of its transmission and the precautions necessary to prevent its spread, and recommending the adoption of certain measures looking to its sanitary supervision.

This communication, which presented the facts in quite the same light as they are now regarded, was printed and widely distributed. Small circulars of in-

formation were also freely distributed in the tenement-house districts, and the public press was utilized for the education of the public as to the communicable nature of tuberculosis. No further action, however, was then taken, as it appeared evident to the board after investigation that the time was not yet ripe for more active measures.

In 1893 the subject was again brought to the attention of the board of health by the writer, and the direct though limited control of pulmonary tuberculosis by the department of health was again urged. The recommendations then made, after careful consideration, were adopted and were put into force under resolutions of the board of health. These resolutions *required* all public institutions in the city to promptly report to the department all cases of pulmonary tuberculosis coming under observation, and *requested* all physicians to report the cases occurring in private practice. They provided for the bacteriologic examination, without charge, of sputum from cases occurring in private practice; for the visitation and instruction of cases not under the care of private physicians, and residing in tenement houses, boarding houses or hotels; for the inspection and disinfection, or, if necessary, the renovation of premises when vacated by consumptives, either by death or removal, and for the disinfection by the department of infected bedding, clothing, etc.

In other words, these measures included partly compulsory and partly voluntary notification and registration, visitation and instruction of the sick, the inspection, disinfection and renovation of premises, and the free bacteriologic examination of sputum from suspected cases. In the establishment of municipal bacteriologic laboratories and in the devising of methods for municipal diagnostic work in bacteriology, as well as in the adoption of these measures for the supervision of tuberculosis, New York City led the way and set an example which has been widely followed throughout the world.

In January, 1897, on the writer's recommendation, the board decided that the time had arrived when the measures carried on under the resolutions passed in 1893, as described above (which had met with but little opposition and had proved increasingly efficient), should be given increased legal force by the adoption of an amendment to the sanitary code of the department relating to the control of this disease. Accordingly, a section was added to the sanitary code declaring pulmonary tuberculosis to be "an infectious and communicable disease—dangerous to the public health," and requiring physicians and others to report to the department all cases coming under their observation.

In this section of the code a broad distinction was intentionally made between tuberculosis—a communicable disease—and those diseases, such as smallpox, scarlet fever, etc., which are properly classed as contagious.

I have always felt that much harm has been done by calling tuberculosis a contagious disease; it produces confusion in the minds of both the laity and the medical profession, because the conception of a contagious disease is always related to such diseases as scarlet fever, smallpox, etc., in which very limited contact or even simple proximity may result in their transmission. Every intelligent person knows that tuberculosis is different in nature from these diseases, and I believe that this distinction should be made and kept clear and definite. Tuberculosis is communicable, but not contagious in the sense that this term is generally employed, both by the medical profession and the laity.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee: Drs. Arthur R. Reynolds, George Cook and Heman Spalding.

The ordinance adopted in New York City in 1897 reads as follows:

Resolved, That pulmonary tuberculosis is hereby declared to be an infectious and communicable disease, dangerous to the public health. It shall be the duty of every physician in this city to report to the Sanitary Bureau in writing the name, age, sex, occupation, and address of every person having such disease who has been attended by or who has come under the observation of such physician for the first time, within one week of such time. It shall also be the duty of the commissioners or managers, or the principal, superintendent, or physician of each and every public or private institution or dispensary in this city to report to the Sanitary Bureau in writing, or to cause such report to be made by some proper and competent person, the name, age, sex, occupation, and last address of every person afflicted with this disease, who is in their care or who has come under their observation, within one week of such time. It shall be the duty of every person sick with this disease, and of every person in attendance on anyone sick with this disease, and of the authorities of public and private institutions or dispensaries to observe and enforce all the sanitary rules and regulations of the board of health for preventing the spread of pulmonary tuberculosis.

I may say that when this ordinance was adopted every important medical society in New York City protested against the action of the department of health, but these protests showed by their wording and the remarks accompanying them that the protestants did not understand the scope of the action of the department of health, and that they had arisen in protest against an imaginary evil. They protested against tuberculosis being called a contagious disease, but the department of health never called tuberculosis a contagious disease, and expressly stated that it was communicable and infectious, but not contagious. A determined but unsuccessful effort was then made by the New York County Medical Society to obtain legislation which would deprive the department of health of the power to deal with tuberculosis. During the last two years, however, there have been few protests against the action or attitude of the department; there has been acquiescence, and apparently approval, and it is certainly true that the action of the department has been followed by greatly increased interest and knowledge regarding the disease, and by the institution of active measures in the state and in the city looking toward its care and its prevention.

It is true that the department of health has not endeavored to enforce strictly the regulations. It was not the intention to do so when they were enacted. It has not prosecuted physicians who have failed to report cases; the board is well aware of the fact that large numbers of cases are not reported; but still a constant advance is being made. The attention of physicians who report deaths due to tuberculosis in cases which have not been previously notified is called by special letter to the provision of the sanitary code requiring the reporting of such cases, and they are asked for an explanation for the failure to report the case. A second letter has been rarely required. The superintendents of public institutions are constantly reminded of their obligations in this matter, and usually twice a year a census is made of all the cases in all the public institutions in the city.

During 1894, the year in which registration was begun, 4,263 cases were reported; three years later, in 1897, 9,572 cases were reported, and in 1901, 17,588 cases (including 4,191 duplicates) were reported to the department. During the whole period since the beginning of 1894, nearly 90,000 cases have been reported.

The records of living cases and of deaths are preserved in two card indices—one, a name index, arranged alphabetically, and the other a street index, arranged by streets and by the house number in each street. Dead

cases are entered on blue cards and living cases on pink cards. In addition to the name and address there are entered on the cards the age, sex and occupation of the individual; in living cases also the institution from which reported and the date of report, and in dead cases the date of death. The registry finally is made more complete by platting all cases on a series of maps, which cover the whole of Manhattan Island. There are one hundred and ten of these maps bound in atlas form. They were made under the direction of the department, and each one, three by two feet in size, is drawn to a scale of one hundred feet to an inch. This scale is large enough to show every house lot in the city by an area in which can be platted forty cases of tuberculosis. The maps are so arranged that they represent the sanitary districts of the United States census of 1890. These districts are supposed to contain a more or less homogeneous population. The entry of cases is made by conventional signs, which indicate the month and year of report, and whether the case is living or dead. On these maps each case reported is indicated by a dot. These show that on a single street block as many as 102 cases have been reported within a period of $4\frac{3}{4}$ years, and as many as 24 cases in a single house. For example, on the block on Cherry Street, between Pearl and Roosevelt, 102 cases came to the notice of the department from April, 1894, when this work was begun, to Jan. 1, 1899. The population of this block in January, 1900, as enumerated by the sanitary police of the department of health, was 1,165. On another block bounded by Cherry, Market, Catherine and Monroe Streets, there were 241 cases of tuberculosis, with a population of 3,688. In a third one, which includes particularly the Chinese quarter, bounded by Chatham, Mott, Bayard Street and the Bowery, there were 206 cases, with a population of 2,102. These districts represent perhaps the worst conditions existing in the city, but the number of cases in many others nearly approximates the number found in these. And throughout the tenement-house districts everywhere large numbers of cases have been reported. I presume we must add to these numbers at least one-half as many more to cover the unreported cases, for I do not believe more than two-thirds of the cases in Manhattan and the Bronx were reported when these maps were made.

With a problem of such magnitude as is here presented, how are the authorities to obtain information in regard to the cases without compulsory notification and without knowledge; how can they hope to deal with any measure of success with the existing conditions? I have never heard those who object to registration suggest any practical alternative, and I believe there is none to be found. It may be said that such conditions as have been described do not exist in this country outside of New York City. Perhaps this is in a measure true; but no one can foresee what will be found in any city until the cases are registered, and I have no doubt that conditions approximating those present in New York City would be found in every large city.

Aside from the greater readiness to report cases, an evidence of increasing confidence on the part of the profession in the attitude of the department of health with regard to the control of this disease, is afforded by the increase in the number of specimens of sputum sent for examination; each specimen which contains tubercle bacilli, representing as it does the report of a case. These specimens have increased in number from 511 in 1894 to 6,744 in 1901, and in the present year, judg-

ing from the first five months, they will probably number more than 7,500.

With certain exceptions, such as patients under the care of private physicians, all reported cases, living or dead, are assigned to the medical inspectors of tuberculosis for the district from which the cases are reported. The inspector visits the address given, and, if the patient is living, leaves a circular of information and gives verbal instruction to the friends about the danger of infection and the care of the sputum. If the address is that of a dead patient, or if the patient, though living, has moved, the inspector examines the premises and makes such recommendations as seem to him necessary to render the habitation free from danger of infection. These recommendations, made out on a prescribed form, usually advise the following routine treatment of apartments: Kalsomined or whitewashed walls or ceilings are washed with a solution of washing soda (one-half pound to three gallons of hot water), and then kalsomined or whitewashed again; paper walls or ceilings are similarly washed and repapered; the woodwork is scrubbed with the soda solution and repainted. The inspector's recommendations are forwarded to the board, and on them as a basis a ten-day order is issued on the landlord requiring him to carry out the specified renovation. The execution of the order is then (as with all others of the board) placed under the supervision of the sanitary police. The premises are reinspected, and if, at the expiration of ten days, the owner has not complied with the order, it is referred to the attorney of the board for enforcement. This procedure was determined on because of the difficulty of disinfection of apartments in which cases of tuberculosis have been, and the greater efficiency attained by the system of renovation. The method is easy of enforcement, as is shown by the fact that compliance with the order has not been refused in a single case. The chief point of interest in this plan is that renovation rather than disinfection is called for. Disinfection involves the use of materials and methods which are not universally familiar. The method of renovation required is understood by all, and is more efficient than any method of disinfection which could be employed; and, finally, disinfection often leaves the apartment in an undesirable condition, while renovation is, of course, always appreciated by the tenant. It is in line with this policy that soda solutions are advised for use instead of sublimate solutions. Soda is an efficient cleansing agent, is familiarly known, is usually in the house, and is comparatively inexpensive; and, finally, will be used, and used in sufficient quantity, while more expensive and unfamiliar disinfectants would not be employed.

Not only the apartments, but the household goods should, of course, be freed from infection, and the attempt has been made to have goods, such as infected bedding, carpets, etc., disinfected at the city disinfecting station. This, however, has been only partially successful, for often a considerable interval has elapsed between the death of the patient and the visit of the inspector, and the goods have often been washed, destroyed or sent away to be cleaned. Still, when feasible, goods are removed by the department and properly disinfected.

At the same time that the other measures were introduced, arrangements were made for the collection and examination of sputa for the diagnosis of suspected cases of tuberculosis. This measure was designed to give greater accuracy to the work of the health department in dealing with many cases, and to enlist the cooperation of physicians by affording them such assist-

ance in the diagnosis of cases as otherwise would often be beyond their reach. It was in line with the previous work of the department in making, without charge, bacteriologic examinations for the diagnosis of diphtheria. In carrying out this measure well-stoppered two-ounce glass jars are supplied at more than 200 apothecary shops, scattered at convenient points throughout the city. These places are already familiar as depots for the distribution of culture outfits for the examination of diphtheria. With the jars are delivered circulars containing directions as to the collection of sputa.

The daily comparison of the certificates in which death is ascribed to tuberculosis with the indices of reported cases shows that at the present time nearly 80 per cent. of those dying from tuberculosis in the Borough of Manhattan have been previously reported to the department (while living) as suffering from this disease.

In the prosecution of the work as above outlined certain difficulties have been encountered. These mainly relate to the obtaining of a full registration of cases. As yet many private physicians do not report their cases of tuberculosis, although more and more cases are being constantly reported, and the data in a constantly increasing number of cases are being obtained through the sputa examinations. The reports from institutions naturally furnish the largest proportion of the cases recorded, and such reports are in some instances inaccurate. Many cases escape detection on account of the inefficient examination given patients. Incipient tuberculosis is frequently not diagnosed in dispensaries, and occasionally an erroneous diagnosis of tuberculosis is made. The addresses, also, given in many reports need revision. Patients frequently give their addresses wrongly through intention, and perhaps as frequently the clerk records the address incorrectly. Naturally, therefore, many false addresses reach the department and are excluded from the records only by the search of the inspector. Rarely in death certificates pneumonia and chronic bronchitis are given as the cause of death to conceal cases of tuberculosis. An investigation is now made of every death occurring in persons over 15 years of age, to determine if the patient has been previously reported as suffering from tuberculosis, and occasionally such previous reports have been found.

The obvious results of the work done thus far lie both in the reduction of the death rate and in the evident effects in the education of the people as to the infectious nature of tuberculosis and the means to be taken for its prevention, and in the destruction of sources of infection by the renovation of infected apartments. It may be doubted whether any considerable degree of popular information as to the necessity of care for the sputum can be diffused through the non-English speaking inhabitants of the poorest tenement-house districts, recruited as they continually are by fresh supplies of the most filthy and ignorant classes from all parts of Europe; but in the better class of tenements, where the inhabitants speak English, there has been such a spread of knowledge concerning the nature of this disease that in a majority of the cases in many districts the inspectors now find at their first visits that all the precautions advised have been already taken.

Another perhaps not unimportant result of the work in New York City is the influence on the action of other sanitary authorities. Similar measures have been adopted by the New York State Board of Health, and the measures and circulars of the New York City Board

of Health have been closely followed by sanitary authorities in many other cities, both in this country and abroad and by state boards in other states. Still the work of restriction of tuberculosis even in New York has but just fairly begun. Among the most pressing needs of the future are larger and better equipped hospitals for the treatment of advanced cases, municipal sanatoria outside of New York, for the care of incipient cases, the inspection of factories, shops, and all other places where phthisical patients may be found, and a more strict enforcement of the sanitary ordinance prohibiting spitting in these places, in all places of public assembly, in the public halls of lodging houses, hotels and tenement houses, and in the means of public conveyance.

The death rate from all tuberculous diseases in the boroughs of Manhattan and the Bronx (old New York) was as follows: 1886, 4.42; 1887, 4.06; 1888, 3.99; 1889, 3.86; 1890, 3.97; 1891, 3.55; 1892, 3.51; 1893, 3.16; 1894, 3.35; 1895, 3.11; 1896, 2.98; 1897, 2.99; 1898, 3.08; 1899, 3.08; 1900, 3.01; 1901, 2.89.

The diminution in the death rate, as shown in the above table, still continues. During the first six months of 1902 4,673 deaths from tuberculosis occurred, equaling a reduction of 10 per cent. on the death rate for 1901, which was the lowest ever recorded, not only for the whole year, but also for this period of the year. It seems evident that sure progress is being made, and that with the cordial support of the medical profession, as a whole, which is now freely accorded by the best elements in the profession, followed as this must be by the universal popular appreciation of the true nature of tuberculosis, in place of the unreasoning fear or careless ignorance which has largely prevailed, we may confidently anticipate as the result of continued effort the almost complete eradication of this, the most fatal disease with which sanitary authorities have to deal.

DISCUSSION.

DR. S. A. KNOPP, New York.—The inauguration of the anti-tuberculosis measures in New York City commenced with Dr. Biggs writing that popular leaflet of instructions regarding the prevention of consumption, which has since been copied by so many cities and states and even by foreign countries. It was originally issued in German, Italian and Hebrew, and was largely distributed throughout the tenement districts of New York. It has very properly been looked on as a model by boards of health engaged in the preparation of such instruction leaflets. In regard to reporting cases to the board of health, I can endorse what has been said by Dr. Biggs. While seemingly compulsory the ordinance in reality makes it optional. Every physician is left free to deal as he pleases with his own cases. There is no interference if the physician does not desire it, and there can not be the slightest objection to reporting cases under such conditions.

Through this system of reporting cases the board of health collected a great deal of valuable information concerning affected districts, and in this way was able to get remedial measures employed. Dr. Biggs has not mentioned one of the most important results which came from the inauguration of this work. I refer to the tenement-house committee. It was shown by the statistics collected that very many cases of tuberculosis existed in certain congested districts. The result was that a most vigorous agitation for tenement-house reform was started and that we have now one of the best tenement-house laws that ever existed. Houses where there is no light and no air and where the sanitary conditions are bad are no longer tolerated. I was exceedingly pleased to hear Dr. Biggs point out the difference between contagious and communicable diseases. He is my teacher—I am proud to recognize him as such, and I know the great pains he has taken to bring this matter before the public. Tuberculosis is not a contagious disease, but a communicable one—the touch of the consumptive is not danger-

ous. Sanatoria are the best places in which not to catch consumption. You can not say the same of smallpox, which is contagious, and the distinction is one which it is important to bear in mind. Tuberculosis is a communicable, preventable and curable disease, but I repeat not contagious, that is to say, transmitted through contact *per se*. From the way some people, including physicians, have treated this subject it would seem that we have to recognize the existence of a new disease, which might very justly be called phthisiophobia. It is a disease from which many people have been suffering of late.

In regard to another matter of great importance and moment concerning efficacious prophylaxis, I should like to make a suggestion. After a death from tuberculosis is reported to the board of health we hear complaints that there is sometimes considerable delay before an inspector can visit and fumigate the premises. Would it not be possible to utilize the telephone or the telegraph in such cases, even if the health department paid the expenses? Delay is dangerous; poor people will remove bedding and clothes.

I am also very much in favor of the establishment of city dispensaries for the express purpose of dealing with ambulant tuberculous cases. It seems to me that such institutions would be of great value as educational and preventive factors as well as in other ways.

DR. P. M. CARRINGTON, Ft. Stanton, N. M.—I would like to ask the Doctor whether he has provided any public places where the public may spit. People, at all events some people, must spit somewhere, and if you do not provide any accommodation for them they will spit on the street. I notice that in New York City a distinction is drawn between the sidewalk and the street, but the sputum may be as dangerous in the one place as the other. If you could devise a scheme by which you would have a sufficient number of destructible receptacles you would get rid of a great deal of material which otherwise may carry contagion.

DR. J. W. GUEST, Louisville, Ky.—It so happens that Dr. Biggs' name is on my diploma also, but, apart from that, I have taken a great deal of interest in the campaign against tuberculosis which he has been carrying on. My report in regard to what we have been doing in Louisville must be very meager. The only thing we do is to send postal cards to physicians asking them to notify us of cases of tuberculosis, and the poor cases we isolate as far as possible in the city hospital. Apart from this, and the free examination of sputum, we do nothing directly in regard to consumption, but we are paying more and more attention to the enforcement of the pure food laws, and thus what we neglect in regard to the former we more than make up in the latter.

DR. B. W. STEARNS, Binghamton, N. Y.—Some encouragement is no doubt to be derived from the statistics quoted by Dr. Biggs, which show a decrease in the proportion of deaths from tuberculosis, but there was one point he did not touch on at all. A good number of the tuberculous patients of New York City remove to Sullivan County and not a few of them die there and their deaths are certified in that county and not in the city. Personally, I know of several cases of the kind during the year 1900, though I am not aware whether or not they are sufficient to affect the percentage.

DR. C. B. JOHNSON, Champaign, Ill.—The Doctor said he used carbonate of soda instead of some more powerful disinfectant. I should like some further particulars—both as to the reason for using the mild disinfectant and the manner of using it.

DR. A. R. REXNOLDS, Chicago—This question of whether tuberculosis should be made a reportable disease is one that has agitated officers of health in this country and abroad for a long time. The profession of Chicago up to this time have never felt that this ought to be done, and officially, as commissioner of health, I have never been able to bring myself to the point of deciding that the disease should be made reportable. The chief objection that we have to doing so is that alluded to by Dr. Biggs, viz.: that it puts tuberculous patients in the same class with those suffering from contagious diseases. A tuberculous patient may live for twenty years following some useful

occupation and mingling with his fellow creatures without any injury or danger to them, provided reasonable care is taken of his sputum. He ought not to be branded as a leper, or classed with patients suffering from smallpox, bubonic plague and other contagious diseases. If a consumptive, and the general public could be brought to understand that there is no danger from contact with a consumptive person—that the disease in short is not what is usually considered contagious—the objection to making it notifiable might ultimately die out. Even in England we know that there has been a great deal of difference of opinion on this point. To me it seems that each community must regulate it according to its own needs. In New York City the reporting of tuberculous cases under the conditions described has proved a good thing, but whether it would be a benefit to other communities differently situated is a question on which much could be said, and I repeat that it seems to me that every community must decide the matter for itself.

I commend most heartily the paper of Dr. Biggs in its entirety. The figures are most striking and convincing, and demonstrate the undoubted advantage of reporting such cases in New York City. Although we have a large population in Chicago it is not so congested as in New York. It is most dense in the sixteenth ward, but there are very few tenement houses such as are known in New York. The buildings are nearly all detached two-story houses, with light and ventilation on all four sides.

The great advantage that has been derived from this pioneer work of the New York Board of Health, lies in the influence it has exercised and the stimulus it has brought to bear on other places. This influence is not bounded even by the confines of the country. In several countries of Europe it has also been felt, and at the tuberculosis congress in London last year Dr. Biggs' name was mentioned by the celebrated Koch himself as that of a man to whom all sanitarians were indebted.

For the present we must leave each community to decide for itself such matters of detail as placing the disease on the reportable list. One other objection occurs to me in regard to making tuberculosis reportable and that is, that if the disease is reported it is implied that the authorities will do something. If these cases are simply reported and a record made of them no great good will be done. Yet in Chicago that would have to be the result at present for lack of men and means. No doubt if it could be reported without giving offense to the patients and without doing harm to any one it would be very desirable. It may come to that, but we must not go in advance of public sentiment; we must try to do the best we can under existing circumstances. We in Chicago rely largely, as Dr. Biggs has mentioned, on taking the public into our confidence through our bulletins of information. We are in the habit of issuing a bulletin each week. It is printed in the daily papers and the publishers give us as many galley proofs as we wish for distribution. One editor told me that the bulletin is regarded as one of the most important items published in the Chicago papers on Monday mornings. It is extensively copied and commented on. All of which shows that the importance of public health is growing daily in public estimation. The people are becoming more interested in it and getting into the way of discussing it more intelligently. For a time there seemed danger that the unreasonable fear of germs would do harm, but this is an evil which has to a large extent cured itself. I am glad that Dr. Biggs made the point that consumption, so far as contagion is concerned, is not the dangerous disease that it is supposed to be, and I have no doubt that once it comes to be understood that the object of reporting is not to hamper the movements of a tuberculous patient, but is really to benefit him, and allow him full liberty so long as he takes care of his sputum, their objections to reporting the disease will be very largely withdrawn.

Dr. BIGGS.—In regard to the reportability of tuberculosis it seems to me that we must get away from the idea which has prevailed among medical men and sanitary authorities, as well as among the public, that reported diseases are necessarily contagious. In my opinion all diseases which are in any sense preventable should be put on the reportable list. It is neces-

sary to get rid of the idea that the fact of their being so dealt with indicates that they have to be classed with smallpox and other diseases of that kind. In New York City we have passed a resolution in favor of putting malarial fever on the reportable list, and of course we do not propose to put it in the same class with the diseases referred to, nor do we propose to interfere with physicians handling their own cases in their own way. All we want is to obtain information as to where these cases occur so that we can gather data as to the sanitary conditions and surroundings, and in this way obtain something to go on in our enquiries as to the underlying causes of the disease. In some of the outlying boroughs where malaria exists to a greater extent than on the island of Manhattan we found that the presence of stagnant water was an almost constant condition, and in some of these districts it appeared that almost every person had been, or was, affected by the disease. We want reports of these cases in order that we may be able to remove the objectionable conditions and so prevent the extension of the disease. A proposition has also been made to make pneumonia reportable, and I certainly think it ought to come within the class. We know the destruction of life that is caused by the disease. We also know more or less how to treat it. But we want to know more about it epidemiologically. We can only do this if we first of all get information as to its distribution in large centers of population. Eventually, in my opinion, all infectious diseases—all diseases which are produced by micro-organisms—will be recognized as reportable, which means that we will get away from the idea that only those diseases should be reported which involve danger by simple contact.

A word in regard to dispensaries: I heartily agree with Dr. Knopf as to their value and necessity, and I may say that we have under consideration a proposition for the establishment of such institutions under the department of health. The plan has not been worked out yet, but the problem is one of those which we hope to solve in the early future.

In regard to the distribution of sputum in public places I do not quite agree with Dr. Carrington that it is as objectionable on the street as it is on the sidewalk. The special danger from sputum on the sidewalks lies in the possibility of its soiling the clothes, especially of women, and of being thus carried (as well as by shoes) into the household. When it is deposited on the street and mixed with the soil and exposed to the light I do not think it is so much a source of danger. It is rather a general nuisance than the source of special infection. On the other hand, great danger is to be apprehended from indiscriminate expectoration in halls and on stairs of buildings used for educational purposes or amusement. It is in these places that one finds the really dangerous centers of infection. If the sputum is deposited on the street it is clear that it can not be nearly so dangerous. All our regulations should, so far as possible, be carried out on grounds of general cleanliness. In ferry boats we require that proper receptacles be provided. Perhaps they are not all they should be, but for the time they are the best we can get.

As to disinfection, the difficulty of the problem is this, that although we have an appropriation it is not sufficient to enable us to cover the work. When we have 400 or 500 cases of tuberculosis to deal with each week and from 1,500 to 2,000 cases of contagious diseases a week are reported the magnitude of the problem of inspection and disinfection becomes apparent. This is the cause of the delay which has been referred to. We have not the force or the facilities necessary to enable us to deal promptly and properly with this phase of the question.

With regard to my advocacy of soda solutions my idea has always been that real cleanliness was preferable to probably inefficient disinfection. Therefore, I say that in the majority of instances hot soda solutions will be found much more satisfactory than bichlorid or any other disinfectant, as used. We should encourage the people to clean rather than to use disinfectants.

As to the reliability of the statistics I have quoted there seems to be no way by which we can eliminate all sources of error. But there are always two sides to a question, and while it may be true that a good many people leave the city when they

are ill and die outside its boundaries, it is no less true that a great many others come to the city sick and die there. This matter has been gone over very carefully, and the conclusions arrived at are that the deaths of this kind taking place in and out of the city pretty well balance each other. After all, however, the number of such cases is so small that it could hardly be expected to affect the percentage. As to the admirable work done by the Chicago Board of Health by means of its weekly bulletin—which is a model publication of its kind—I may say that we have under consideration the adoption of some similar plan for the weekly discussion of sanitary problems. Before closing I would like to say a word as to the excellent work which has been done by Dr. Knopf, and the enormous influence his writings have had in extending a knowledge of tuberculosis and the means to be taken for its prevention and cure.

A PECULIAR CASE OF RECURRENT BULLOUS ERUPTION.*

WILLIAM S. GOTTHEIL, M.D.

Physician to the City Hospital, Lebanon and Beth-Israel Hospitals.
NEW YORK.

It may well be that the case which I shall briefly describe is of a type not unusual in some localities, or that it is not infrequently seen by those who practice in pediatrics. But I have never come across one precisely similar, and its characteristics, both positive and negative, are such that I am unable to classify it under the heading of any of the ordinary dermatoses. These considerations embolden me to place on record the following case:

Mamie K., 5½ years old, was brought to my clinic at Lebanon Hospital, with the following history: Since her second year there has appeared each autumn a skin eruption similar to the one that is now present; during the spring and summer there is absolutely nothing the matter with her integument. Each attack began with the appearance of a few watery blisters, which increased up to a certain size, and then either ruptured or dried up. From time to time new ones appeared, thus prolonging the course of the disease to several weeks or months. Then, quite spontaneously, the blisters ceased to form and the child was well. Subjective sensations were entirely absent, so that the child had had no treatment at all; and the sole reason that she was now brought to the clinic was the fact that the accident of location of some lesions in this attack does give her trouble. The first attack occurred in her second year; there were only two or three small bullæ on the backs of the hands, and the eruption lasted but a short time. The second attack in her third year was a little worse; there were more blisters, their size was larger, and the eruption lasted longer. In the attack of the fourth year the forearm and legs were affected, as well as the hands, and the severity of the symptoms was increased. The present fourth attack is the worst that she has ever had. It has been present since September (over three months); the blisters are larger than they have ever been; some have appeared on the mons veneris and abdomen, and there have been a number of lesions on the buttocks, thighs, legs and arms. Each one takes two or three weeks to run its course, instead of a week, as did the early ones; and new efflorescences are continually coming out, so that since this attack began, there have always been some score or two of lesions present in various stages at least. Within the last few days some large blisters had appeared on the ankles and soles; and the child had been unable to walk on account of the pain that they occasioned.

There had been neither itching nor pain before or after the appearance of any of the lesions. Most of them were accidentally discovered when the child was being dressed or bathed. When rupture of the bullæ had occurred, the skin beneath the detached epidermis was found moderately reddened, but not especially sensitive; the mother usually applied a bandage to

the part for a day or two. There has never been any apparent relationship to pressure or other injury; the blisters have not been commoner around the ankles or waist or on the knees or elbows, than elsewhere; they have never come on after a fall or a bruise. There are no other children in the family, and the mother can give no history of any relative on either side of the family having been similarly affected.

Examination showed the child to be perfectly healthy as regards her internal organs. She is a fairly robust girl of the blond Germanic type, and is physically and mentally normal. The lesions present were almost all on the lower limbs; there are some 50 of them from the hips down. The great majority of these, however, were only the dried remains of smaller blebs, or the fading marks of older ones. There were large bullæ, however, just below the right internal malleolus, on the inner edge of the sole of the left foot, and on the upper thighs. These were the new ones that had appeared during the last few days. On the mons veneris, lower abdomen, and arms only the stains of vanished lesions were apparent.

In the weeks following this first examination, I had abundant opportunity to watch the development of the bullæ from their beginning. Without any local prodromal symptoms, either subjective in the shape of itching, formication or pain, or objective as redness, elevation or whealing, there would appear a minute vesicle, tense, globular, and filled with a trans-

parent yellow serum. This would rapidly increase in size, becoming as large as a bean in 24 hours, and walnut-sized or over in from two to three days if it was not accidentally ruptured. In the case of the bulla of the sole I took care to prevent this happening; and it grew to be as large as a goose-egg, and stretched across the sole. I was then compelled to rupture it on account of the disability that it occasioned the patient. After rupture of the largest bullæ the epidermis could be removed at once, since epithelial repair had largely taken place under it, and the surface was not sensitive.

All attempts on my part to produce bullæ by friction, pinching, etc., were fruitless, thus confirming the mother's statement as to the spontaneous origin of the lesions.

Knowing from the previous attacks that the disease was self-limited, I did not deem it necessary to institute any very vigorous treatment, and put her on moderate doses of arsenic. In January the lesions began to become less frequent, and late in February they ceased to appear. During this period I made it a practice to rupture the bullæ early, and none of them attained any very large size.

Here, then, was a recurrent bullous eruption in a child, coming on in the fall of four successive years, running a definite course, and unaccompanied by the other symptoms usually met in lesions of this nature. It was certainly not an epidermolysis bullosa, for there was no hereditary history, no relationship to injury, and the disease ran a definite course. It was not a

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. W. T. Corlett, L. Duncan Bulkley and W. L. Baum.

bullous urticaria, for there was no itching, and there never were any other urticarial lesions on the child's body; and a similar argument holds for a bullous erythema. Dermatitis herpetiformis is grouped and inflammatory; this eruption had neither of these characteristics. In a female adult an artificial (cantharidal) eruption might be thought of, but it is not possible that a child of such tender years would produce them, and I am very sure that her mother did not do so. I should hesitate to call it a benign pemphigus, on account of its periodicity and the absence of an inflammatory areola around the bullæ. Yet this latter designation is apparently the one that would fit it best, and is the one that I should select, if compelled to make a choice.

DISCUSSION.

DR. L. WEISS, New York—I would like to ask Dr. Gottheil what treatment he has pursued. I saw, in consultation, a similar case of a woman aged about 50, feverish and in a low condition. She had two blebs, one on the outside of the left malleolus of the size of a hen's egg, and a smaller one on the right wrist. I recommended simply a zinc-gelatin varnish, and in a few days under this occlusive application the denuded surface cleared itself, and within ten days the suppurative symptoms subsided, and the integument was replaced.

DR. JAY F. SCHAMBERG, Philadelphia—I should like to report a remarkable case which this paper calls to my mind. I saw a few weeks ago a colored man, aged 21, who exhibited on the palms of the hands and on the fingers numerous blebs varying in diameter from 1 to 2 cm. Lesions of a similar character were present on the lips, tongue and buccal mucous membrane. In the beginning of the attack the patient was obliged to subsist on liquid food owing to difficulty in swallowing. The patient had experienced three distinct attacks of this same character at intervals of six months and a year; in all of these the same regions were involved. The patient had had syphilis. There are many bullous eruptions which are most obscure in their nature and extremely difficult to classify. Many of these are being thrust into the class of dermatitis herpetiformis, thus extending the limits of this disease beyond the boundaries established by Dühring.

DR. M. L. HEIDINGSFELD, Cincinnati—Cases of bullous eruptions are always a matter of peculiar interest by virtue of their obscure nature, and in discussing this paper I wish to briefly mention a case, not only because it is of particular interest to me, but also to determine whether or not any of my fellow members have had a similar experience. A case which has been recently reported to the *Cincinnati Lancet-Clinic* (Aug. 2, 1902) under the name of "Epidermolysis Bullosa (Facilitia)" or traumatic α -ray bullous dermatitis, was exposed to the rays during three sittings of five minutes each, and was followed by slight erythema and a marked tendency to bullous formation over areas subjected to slight trauma. To all intents and purposes this case could be called an artificially-induced case of epidermolysis bullosa, through heredity, its beginning in early infancy and other features were lacking, as in some of the recorded cases of traumatic bullous eruption. The blood showed no variation from the normal, and incidentally I would like to ask Dr. Gottheil if the blood examination, or the contents of the bullæ in his case, showed any interesting changes.

DR. DAVID LIEBERTHAL, Chicago—I have seen a case similar to that of the essayist, through the courtesy of Dr. I. A. Abt. Soon after birth the child exhibited bullæ in the mouth and on the lower extremities. These bullæ had a thin roof and clear contents and soon broke down, healing taking place in a few days. The presence of scars near the ankles was strongly suggestive of syphilis, but no other symptoms were present supporting this supposition. At intervals of months new blebs appeared on the lower as well as the upper extremities, pursuing the same course, although the mouth remained free. The number of blebs at each eruption was limited to from one to three. This case, too, is difficult of classification and further observation might lead to its proper interpretation.

DR. GOTTHEIL—I presented this case as an example of a clinical type with which I was not familiar. In response to the first question I would say that it was undoubtedly self-limited; each of the previous attacks ended spontaneously, without any treatment at all; and the one that I observed had practically no treatment either. I have not seen anything similar from exposure to the Roentgen rays, but I know that such have been recorded. The bullous eruption from α -ray exposure, however, comes on very slowly, lasts a long time, and leads to very intractable ulceration; here the individual bullæ lasted but a very few days, were superficial, healed spontaneously without destruction of tissue, and the malady was prolonged by the appearance of new bullæ on other parts. Besides this, there had never been any exposure to the rays.

The diagnosis apparently lies between a benign pemphigus and a bullous erythema, with some very cogent arguments, however, against the adoption of either designation. It is for this reason that I have regarded the case as worthy of record.

Havana Leper Hospital.—At the meeting of the Orleans Parish Medical Society, Oct. 11, 1902, Dr. Isadore Dyer gave an interesting account of his visit to the Havana Leper Hospital. Although founded in 1681, the Hospital San Lazzaro assumed importance only in 1861, when the present imposing building was erected. This occupies a prominent position on one of the main thoroughfares only a few hundred yards removed from the bay front and opening on a broad plaza. The entrance from the street discloses a large chapel for the use of the public, to which the patients in the hospital have access in a reserved space just off the chancel, separated on each side by high iron railings, one side for females, the other for males. There are in all 114 patients, mostly native, and about equally divided between male and female; only a few children, the youngest about eight years, and only a few negroes. Quarters for the two sexes are separately arranged and a distinct infirmary is provided for those lepers who become ill or some concurrent malady. Seven sisters of charity are in charge of the nursing and domestic departments, and help is received, not required, from those patients who are able to render it. The whole establishment is cleanly and strict attention is given to ventilation and hygiene. As in all Cuban establishments, the bathing facilities are meager. Treatment at this institution seems to present about the same results as is common elsewhere. Most reliance is placed by Dr. Alfonso, the head of the hospital, on Chaulmoogra oil, and he believes his best results are obtained with this remedy. Experimental work has been done for the past eight months with red mango bark, but as yet without result. Baths of benzoinated water, sulphurated water, etc., are employed in some cases. Carasquilla serum has been used and abandoned. Arsenic and bichlorid of mercury are among the other remedies chiefly employed. The salicylates and ichthyol are also used. Strychnin as a regular treatment did not seem to appeal to Dr. Alfonso as it has to Dr. Dyer, for the latter has always held strychnin as a sheet anchor in leprosy, and has never treated a case without maintaining this drug throughout, no matter what else he may have used. Dr. Dyer was struck, in the short time at his disposal to observe these patients, with the large number of pure tropic types, the sort of cases found in Brittany and in Constantinople, those cases which have led to the separation of Morvan's disease as an entity. Of all the cases shown him at the San Lazzaro Hospital, there were few of the tubercular type, the type in which the bacilli are found freely colonized. The fact that so many of the cases were natives and that they presented for so large a part the evidences of what Zambaco-Pacha has called "effetex" leprosy, possibly explains the fact that there is no instance recorded of contagion having occurred among the attendants of this institution. Altogether the appearance and detail of the Havana Leper Hospital, and it is not an asylum, impressed the doctor with the highest sense of respect for a well-organized and managed institution.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

SATURDAY, DECEMBER 27, 1902.

THE CURRENT INDEX.

Much of our space this week is taken up with the index, consequently several of the departments are omitted and those that are given space are greatly reduced in quantity.

In this connection we desire to call attention to one part of the index which we issue with each half-yearly volume, as it is a distinct feature, unique to this journal only. We do this because we find that comparatively few of our readers appreciate what we are doing in this regard; and as it requires a large amount of labor, we do not want these efforts lost. We refer to the Index of Current Medical Literature. This will be found on index pages 1671 to 1698. In the index in this volume will be found for the second time the references to all the important articles in the leading foreign journals, making the index a practically complete index of the current medical literature of the world. The directions for using the index will be found on page 1671.

To make this of still more value we shall reprint this index in pamphlet form, together with all the titles of papers, name of journal in which they appeared, etc., under the title, "Index of the Current Medical Literature of the World." This will make reference easy, and will, we are sure, prove acceptable to those who have occasion to look up the current literature. We do not hesitate to say that in the near future a file of these indexes will be valuable. The price is twenty-five cents, which barely covers the cost to us.

THE IMPORTANCE OF SCIENTIFIC GUIDANCE IN SANITARY UNDERTAKINGS—A WARNING.

The comprehensive review by Professor Jordan of the present, most interesting conditions in Chicago as regards water supply, which appeared in *THE JOURNAL* last week,¹ makes highly instructive reading. People have heard and read so much about the great Chicago Drainage Canal, "the greatest engineering feat of modern times," that it comes very much like a shock when one is told by competent authority, backed by undeniable testimony, that from a sanitary standpoint the canal is a failure, a blunder; that after an expenditure of forty to fifty million dollars the city of Chicago is without wholesome water; that typhoid fever, the infallible curse of sewage polluted drinking water, still is and has been rampant in the city, which continues to be a center for

dissemination of typhoid bacilli to all parts in the surrounding country. It is humiliating and in every way unpleasant to know that the most progressive of cities should fail so utterly in its grandiose effort to render itself healthful.

But the truth in such matters should be told as directly and plainly as possible, without any sugar coating, so that proper warning is given and that other cities may profit by avoidance of the Chicago blunders. The cause of the sanitary failure of the Chicago Drainage Canal does not lie in any inability on the part of the engineers to cope successfully with the difficult problems in engineering. From the standpoint of the canal builder the canal is a creditable success. The project of a great sanitary drainage canal, which should carry the Chicago sewage into the Illinois and Mississippi rivers instead of allowing it to empty into Lake Michigan, whence the city obtains its water supply, meant in reality nothing more and nothing less than an effort to free Lake Michigan, at least in the vicinity of Chicago, from sewage pollution. It was in advising this undertaking that the projectors of the drainage canal took on their shoulders greater responsibility than was warranted by modern sanitary knowledge in general, and especially in regard to the best methods of sewage disposal and the obtaining of healthful water. It is probably safe to say that if the entire situation had been critically and carefully studied by a board of competent sanitary experts, with modern training in such matters, the construction of the present canal for drainage and sanitary purposes only would probably not have been recommended. But in the history of the present drainage canal, from its inception to its completion, the bacteriologist and scientific sanitarian is conspicuous by his absence. Does any one for a moment believe that a careful and competent study in a comprehensive manner of the local situation would have permitted the construction of the canal and its opening with a great flourish of trumpets while the sewage of a large part of the city was still emptying into the lake, which is the common source of supply for the whole city? Only incompetence and ignorance can explain such lamentable oversight as this, leaving aside for the moment all discussion of the best general principles of water supply and sewage disposal.

Then, again, as pointed out clearly by Professor Jordan, the present drainage canal in no way prevents the contamination of the lake water by the sewage of the towns at the northern and southern extremities of the city, as well as by that of those parts of the city itself. What guarantee is there that when Chicago, after years of labor and the further expenditure of millions of dollars, shall have turned its last sewer into the drainage canal, the lake water may not still be contaminated by surface drainage, by passing vessels, and, of more importance, by the sewage of cities and towns in Wisconsin and Indiana?

1. *THE JOURNAL A. M. A.*, Dec. 20, 1902, p. 1561.

There seems to be no escape from the remedy suggested by Professor Jordan, namely, sand filtration. Would that it had been resorted to long ago! We unhesitatingly affirm that the truly pitiable condition in which Chicago finds itself to-day so far as water supply is concerned, is in large measure the result of hastily entering on sanitary undertakings of wide scope without the great advantage of expert scientific guidance and careful, comprehensive study of the problems involved in all their bearings. Chicago entrusted the problem of freeing its water supply from sewage contamination to men without any special training or experience whatsoever in the branch of knowledge most important to its solution, namely, sanitation, with the result that so far its water supply has not been materially improved, even after the construction of a gigantic canal. To what extent the medical profession is blamable for this failure because its members did not interest themselves enough in the matter it is not necessary to discuss now, but it may be hoped that the present plight of Chicago will prove a warning to other cities about to embark on similar sanitary undertakings.

Medical News.

CALIFORNIA.

Sisters' Hospital Annex Opened.—With solemn ceremonies the addition to the Sisters' Hospital, Los Angeles, was opened December 11.

Personal.—Dr. Edward M. Pallette, Los Angeles, has returned from a year's trip around the world.—Dr. Thomas Nelson, recently graduated from Cooper Medical College, is the first colored graduate of that institution. Dr. Fred A. Grazer, San Francisco, recently dislocated his shoulder and fractured his left arm by a fall from a street car.—Dr. Edith H. Matzke, Stanford, has been appointed to a position in the department of hygiene at the university. Her duties will be to give hygienic and medical advice to the female students.—Dr. Julius A. Crane, Agnew, has resigned as medical superintendent of the Agnew State Hospital.—Dr. Andrew S. Lobingier, Los Angeles, has returned from a six months' tour of Europe.

COLORADO.

Deaths in November.—During November 810 deaths were reported in the state, equivalent to an annual death rate of 16.8 per 1,000. Typhoid fever caused 60 deaths, diphtheria 22, and scarlet fever 3.

New Law in Force.—The new regulation requiring all invalids boarding trains in Colorado to be provided with a physician's certificate stating that they have no contagious disease became operative December 6.

Alleged Violation of Law.—The district attorney has filed information against Mrs. Serada H. Callanan, charging her with practicing medicine without a license and with illegally attaching the letters "M.D." and prefixing "Doctor" to her name.

Comparative Morbidity.—During November 183 cases of diphtheria, 134 of scarlet fever, 46 of smallpox and 468 of typhoid fever were reported. Compared with October, this shows an increase of 76 cases of diphtheria, 22 cases of scarlet fever, and 21 cases of smallpox; and a decrease of 187 cases of typhoid fever.

INDIANA.

Thousands to Hospital.—On November 30 the relatives of the late Clem Studebaker presented \$50,000 to Epworth Hospital, South Bend, in accordance with the expressed desire of Mr. Studebaker.

Illegal Practitioners Punished.—The Circuit Court has found G. W. Ober, Indianapolis, and W. G. Richardson, Jeffersonville, guilty of practicing medicine without a license and has fined them respectively \$207 and \$47.

Smallpox.—During October 298 cases of smallpox occurred in 35 counties in the state, with 19 deaths. In October, 1901, 113 cases were reported from 9 counties, with two deaths.—On December 16 it was reported that there were 50 cases of the disease in Hammond, which had been diagnosed, as usual, as "Cuban Itch."

NEW YORK.

New York City.

Bequest to Hospital.—Among other bequests to charities by the will of the late Anne Lawrence Coleman is one of \$5000 to the babies' ward of the New York Post-Graduate Hospital.

St. Francis' Hospital.—The cornerstone of the new hospital was laid, December 8, with short and simple exercises. The new hospital will occupy all the large block in the Borough of the Bronx bounded by 142d and 143d streets, and Brook and St. Ann's avenues.

Conditional Gift to Seney Hospital.—At the anniversary dinner of the hospital, December 15, William Hulls, Jr., agreed to complete the buildings and grounds of the hospital at a cost of \$125,000 provided that prior to June 1, 1903, the sum of \$50,000 be raised in bona fide subscriptions.

Schedule for Dr. Lorenz.—Dr. Adolf Lorenz reached New York City on December 13. On Monday afternoon, December 15, he held a clinic at the Hospital for Ruptured and Crippled; on Tuesday a clinic at the New York Polyclinic; on Wednesday at the Post-Graduate Hospital; on Thursday at the Cornell Medical School; on Friday at Bellevue, and on Saturday at the College of Physicians and Surgeons.

OHIO.

Itinerant Arrested.—W. B. Georgia, an itinerant medicine man, was recently arrested at Findlay on the charge of practicing medicine without a license from the state. He was released on \$100 bonds.

Resolutions Regarding Dr. Carpenter.—At the meeting of the Ohio Medical University board of trustees, at the Park hotel, resolutions were adopted on the death of Dr. Eugene G. Carpenter, late superintendent of the Columbus State Hospital, who was a member of the university faculty.

Polyclinic.—The staff of the new polyclinic is announced as follows: Drs. Henry A. Ingalls and Travis Carroll, surgery; Drs. Edward M. Keefe and Frederick Bacharach, medicine; Drs. Samuel Rothenberg and L. J. Clark, obstetrics; Dr. Oscar W. Stark, eye and ear; Drs. Adolph Morgenstern and William D. Haines, nose and throat, and Drs. Edwin S. Ricketts and Charles T. Pearce, abdominal surgery.

PENNSYLVANIA.

Equips Surgical Ward.—At a cost of several thousand dollars, Col. G. S. Beck has presented the surgical ward of the Reading Hospital with an entire new equipment.

Contract Awarded.—The contract has been awarded for \$125,000, to build eight steel and glass pavilions for the treatment of consumptives at the Philadelphia Hospital.

Pathologic Exhibit.—The annual exhibition meeting of the Philadelphia Pathological Society was held December 11, in the Mutter Museum of the College of Physicians. There were good displays of series of microscopic specimens, but the exhibit of a series of gross specimens was most excellent.

Insects and Disease Transmission.—On December 12, under the auspices of the Stillé Medical Society of the University of Pennsylvania, Dr. L. O. Howard, entomologist of the Agricultural Department at Washington, gave a very excellent illustrated lecture on "Some Insects Concerned in the Transmission of Disease." The speaker dealt chiefly with the mosquito in the transmission of malaria and yellow fever.

Deaths.

Josiah W. Lash, M.D. Columbus (Ohio) Medical College, 1878, a member of the American Medical Association, died at his home in Chillicothe, Ohio, December 12, from angina pectoris, aged 50.

James F. McCone, M.D. University of California, San Francisco, 1892, a member of the American Medical Association, died in San Francisco, December 7, from tuberculosis of the hip, aged 31.

Joseph Charles, M.D. College of Physicians and Surgeons, Baltimore, 1881, died at Newport News, Va., December 12, from gastritis, aged 49. He was a member of the American Medical Association.

Adelbert F. Coope, M.D. University of Michigan, Ann Arbor, 1870. a member of the American Medical Association, died in Oil City, Pa., December 14, from cerebral hemorrhage, aged 58.

Thomas R. Veazey, M.D. Kentucky School of Medicine, Louisville, 1885, of Milan, Ind., died at Pittsburg, Pa., December 10, from anemia following malarial fever, aged 45.

Bartus Trew, M.D. College of Physicians and Surgeons, Baltimore, 1890. died at his home in Baltimore, December 12, from endocarditis, following rheumatism, aged 33.

Francis F. Forwood, M.D. University of Maryland, Baltimore, 1892, of Chester, Pa., died suddenly from heart disease, in Mecklenburg County, Va., December 8, aged 34.

William W. Miller, M.D. Western Pennsylvania Medical College, Pittsburg, died at his home in East End, Pittsburg, December 14, from typhoid fever, aged 36.

Lucius W. Baker, M.D. New York University, New York, 1880, died at his home in Baldwinsville, Mass., December 7, from valvular heart disease, aged 50.

George M. Van Dyke, M.D. Jefferson Medical College, Philadelphia, 1888, died from apoplexy at his home in West Newton, Pa., December 13, aged 44.

Dennis Nunan, M.D. University of Michigan, 1867, and Trinity Medical College, Toronto, 1869, died at his home in Guelph, Ont., December 12, aged 63.

Joseph Adolphus, M.D. Pennsylvania Medical College, Philadelphia, 1849, died from rheumatism at his home in Atlanta, Ga., December 9, aged 88.

John McKinley, M.D. Jefferson Medical College, Philadelphia, died at his home in New Wilmington, Pa., from paralysis, December 12, aged 67.

Homer C. Valentine, M.D. Starling Medical College, Columbus, Ohio, 1898; died from tuberculosis at his home in Stouts-ville, Ohio, December 8, aged 32.

Frank H. Green, M.D. Syracuse (N. Y.), University, 1892, a coroner of Cortland County, N. Y., died at his home in Homer, December 7, from pneumonia.

Alfred J. French, M.D. Vermont Medical College, Woodstock, 1848, died at his home in Lawrence, Mass., December 1, from acute gastritis, aged 79.

William B. Lindsay, M.D. University of the Victoria College, Cobourg, Ont., 1869, died from apoplexy, December 9, at his home in Strathroy, Ont.

Levi J. Hixon, M.D. Trinity Medical College, Toronto, 1888, died at his home in La Salle, N. Y., from carbolic acid poisoning, December 4, aged 42.

Ferdinand Venn, M.D. University of Pennsylvania, Philadelphia, 1892, died suddenly from heart disease in Chicago, December 17, aged 32.

William M. Fulkerson, M.D. New York University, New York, 1881, died at his home in Ingleside, N. Y., December 7, from typhoid fever.

Thomas O. Brewer, M.D. Louisville (Ky.) Medical College, 1881, died at his home in Monroe, La., December 14, aged 51.

John T. Hammond, M.D. Jefferson Medical College, Philadelphia, 1852, died at his home in Berlin, Md., December 6, aged 72.

John W. Gaston, M.D. Hospital College of Medicine, Louisville, 1890, of Troup, Texas, died December 4, from heart failure.

E. B. Davis, M.D. Western Reserve University, Cleveland, 1884, of Kirby, Ohio, died suddenly from heart disease, December 12.

John S. Lewis, M.D. College of Physicians and Surgeons, Baltimore, 1879, died at Weston, W. Va., December 15, aged 43.

Darius D. Deppen, M.D. Pennsylvania Medical College, Philadelphia, 1853, of Bernville, Pa., died December 8, aged 70.

Edward D. Wright, M.D. University of Tennessee, Nashville, 1882, died at his home in Nashville, December 9, aged 55.

Edmund M. Landis, M.D. Rush Medical College, Chicago, 1875, died in Chicago, December 14, from pneumonia, aged 56.

Benjamin Benoit, M.D. New York University, New York, 1877, died at his home in Lowell, Mass., December 7, aged 55.

John Ring, M.D. Rush Medical College, Chicago, 1888, died at Chicago, December 14, from heart disease, aged 74.

James Bartlett, M.D. University of Louisville, Ky., 1878, died at San Antonio, December 13, from sepsis.

Societies.

NORTHWEST MEDICAL SOCIETY OF PHILADELPHIA.

Monthly Meeting, held Dec. 2, 1902.

The President, Dr. Wendell Reber, in the Chair.

Rheumatic Tonsillitis in Children.

DR. JOHN STEWART divided tonsillitis into catarrhal and rheumatic, and stated that while many writers asserted the condition was confined to the membranous portion of the glands many cases had come under his observation which had involved the entire gland. The disease may occur at any age, although most frequent in children between 5 and 15 years of age; the attacks are usually recurrent, with a varying length of time intervening; oftentimes there is a family predisposition. The disease is frequently accompanied by muscular and especially articular rheumatism, and may partake of the nature of an epidemic, more particularly during the rapid weather changes in the fall. It is generally due to a rheumatic poison in the circulation, but chronically enlarged tonsils are very apt to assume this state on the slightest provocation, such as exposure to cold, wet, etc. The symptoms are a sudden onset, severe chills and fever, thirst (due to lessened secretion from the tonsils which afterward becomes increased, but is of a thick tenacious character), headache, loss of appetite, coated tongue, bad taste in the mouth, foul breath, painful deglutition, almost constant desire to clear the throat, and inflammation which has extended to the uvula. Ofttimes there is also earache due to inflammation extending up the Eustachian tube to the ear; and in the severe attacks the liquid nourishment is forced through the nostrils when the child attempts to swallow, owing to the infiltration of the muscles of the palate with serum. The condition may be either unilateral or bilateral, and although only one side is involved at first, it may later extend to the other as well.

The chief difficulty in diagnosis is the differentiation between this disease and diphtheria and pharyngitis, the distinctive features being that in rheumatic tonsillitis the onset is more sudden, the temperature higher and the redness of the throat more diffuse than in diphtheria; and in tonsillitis the yellowish-white spots can be removed from the crypts and will disappear in about two days, while in diphtheria they will continue to reform for one or two weeks. In pharyngitis the extent of the inflammation is greater than in tonsillitis, involving practically the whole pharynx.

In the beginning of the attack calomel, salicylic acid or sodium salicylate will often prevent suppuration, shorten the attack and relieve the pain and inflammation. When the disease has advanced to about the fifth or sixth day ammoniated tincture of guaiac was thought to give almost immediate relief. Local applications of peroxid of hydrogen were recommended after the beginning of convalescence and tincture of ferric chlorid and potassium chlorate to reduce the tissues to their normal size. If suppuration occurs, hot applications should be applied and the abscess opened; the diet throughout the attack should consist principally of gruels, etc.

DISCUSSION.

DR. WILLIAM L. PEPPER felt that there were but few cases of true rheumatic tonsillitis occurring in children, the majority of cases of tonsillitis being caused, in his opinion, by the formation of lactic acid in the stomach, which on its absorption by the tonsils produced inflammation. He recommended local applications of hydrogen peroxid, which tends to antisepticize and oxydize the parts and thus prevent the absorption of germ excretion, biniodid of mercury and in the beginning stages of the disease free purgation by the use of 1/10 of a grain of calomel every five minutes until 1 grain is given.

DR. A. B. KIRKPATRICK believed most cases of tonsillitis were caused by some infection, which is particularly apt to occur when the organs are enlarged and adenoid tissue present. In his experience very few cases of the true rheumatic variety have been observed in children, one reason for this being the fact that children are not, as a rule, excessive meat eaters, which

has some tendency to the production of a rheumatic diathesis. With a family predisposition to a rheumatic or uric acid diathesis, the condition would be more likely to occur. Frequently in a child with enlarged tonsils a slight cold will cause an onset of the disease. Many cases due to indigestion will yield in 24 hours to calomel, phenacetin and bicarbonate of soda. If there is enlargement of the submaxillary or sublingual gland local applications of ice will be of value. Ammoniated tincture of guaiac, iron and chlorate of potash were felt to be of little if any value, and the former, in addition to being of little if any benefit to the disease, was very apt to produce a disordered digestion. In rheumatic tonsillitis, biniodid of mercury and the salicylates were recommended and in cases of abscess formation local applications of peroxid of hydrogen were thought to be of value.

DR. HARRY LOWENBURG stated that in the several cases of follicular tonsillitis on which he had used biniodid of mercury the results had not been very satisfactory. He felt that rheumatic tonsillitis would be difficult to diagnose unless there was a family or previous personal history of rheumatic condition, which in the case of children he thought was more frequently manifested in the shape of growing pains than in cases of acute articular rheumatism.

DR. CARL LEE FELT agreed with the previous speaker on diagnosis. In the infectious variety, local applications are of value, but in rheumatic tonsillitis they should be strenuously avoided. Calomel, sodium salicylate and benzoate of soda are of value. Many cases, if left alone, will get well in seven or eight days. Where there is a bluish appearance of the throat, with considerable pain, no membrane and very little if any swelling, Dr. Felt thought it indicated rheumatic tonsillitis.

DR. SAMUEL WOLFE believed that there were very few cases of true rheumatic tonsillitis in which suppuration was present, those cases being usually produced by infection. Rheumatic conditions of the throat are more apt to attack the pharynx than the tonsils, thus following the rule in other parts of the body that rheumatism is more apt to attack the fibrous portions. The rheumatic variety is usually associated with other rheumatic symptoms in various parts of the body, on inspection there is usually very little if any inflammation, but a great amount of pain, which is decidedly intermittent, and the duration may be for a variable length of time. For the treatment of the rheumatic variety salicylates were recommended as a means of checking the disease for a time and in some cases will probably effect a cure, but as a rule the constitutional seat of the disease must be acted on by some other remedy. With an inflammatory phlegmonous or catarrhal condition, guaiac and the early application of ice, externally and internally, were recommended.

DR. SAMUEL P. GERHARD felt that the term rheumatic tonsillitis was rather a misnomer, except in cases where there was a history of rheumatic diathesis, and stated that in cases where the tonsils were enlarged and inflamed he had obtained good results from the application of adrenalin, administered hypodermically, if the tonsil is very large and patient will not have it excised.

DR. WILLIAM H. GOOD referred to two brothers with histories of gout, one has purpura of the rheumatic type and usually suffers from a bad attack of migraine two or three times a year, the other has rheumatic symptoms and usually has quinsy once or twice a year. Dr. Good suggested a connection between the quinsy and the rheumatic symptoms.

DR. WENDELL REBER stated that he believed the reason children so seldom suffer from rheumatic tonsillitis is the fact that they are out in the open air so much, rather than the restriction of their diet in reference to meat.

DR. STEWART stated that all the cases on which his paper was based had been cases in which the parents gave a history of a distinct rheumatic diathesis, and even although suppuration had existed in some of them he believed them to be of the true rheumatic variety. In regard to the ammoniated tincture of guaiac producing gastric disturbance, he felt that that could be avoided by giving it in connection with some other palliative substance. In regard to the use of adrenalin, he felt that as a temporary means of reducing very large tonsils it was of great

value, particularly in conjunction with a 10 per cent. solution of antipyrin, but that the result would not continue for more than five or six hours, and would need to be repeated.

Gynecologic Specimens.

DR. T. TURNER THOMAS gave a demonstration of a number of fresh gynecologic specimens, detailing the various procedures in operation in such case. The points brought up were discussed by Drs. Wilmer Krusen and Frank C. Hammond.

2. **Laryngectomy.**—Hartley describes the mechanism. The article is to be concluded in a future number.

3. **Genito-Urinary Therapeutics.**—The points discussed by Fuller are the elimination of gonococci, the dissipation of general infection from the tract, sterilization of the tract in connection with operation, and the limits to be put on the administration of anodynes. He is not sanguine in his estimation of the direct elimination of gonococci, and thinks that the expectant treatment, leaving the work to Nature, is sometimes better than the spectacular one which thwarts her. Elimination of the general infection can frequently be accomplished by surgical removal of the primary factor. In the minority of cases hygiene and drug measures will have to be used. Diuresis, drugs to inhibit germ proliferation, vesical and urethral lavage and attention to the general condition are then indicated. Among the drugs urotropin at present stands at the head. He does not any longer attempt complete sterilization of the urinary tract prior to operations, as that is impossible. He believes that ordinary and post-operative antisepsis will often be sufficient and less risky on account of the greater quickness of the operation in certain cases. He particularly objects to opium and its derivatives, thinking they increase the risk. The patient's mind should be alert; if the patient is drowsy and supremely comfortable after operation, Fuller fears uremia.

4. **Rectal Stricture.**—Ries describes a new method of relieving rectal stricture by shutting off the bowel above the stricture and pulling down on the upper portion, anastomizing it with the lower portion of the rectum. The details of the operation are described, and schematic illustrations given showing its method and results.

6. **The Climate of Porto Rico.**—Groff thinks there is no process of acclimatization to persons from a temperate climate in Porto Rico. The trade winds prevent the heat and humidity being oppressive. San Juan is a hot city on account of its being closely built with brick; in other places one needs blankets at night. There are no diseases which one from temperate latitude need fear. Tuberculosis is prevalent owing to the low state of nutrition and the less resistance of the natives. Dysentery is localized, as is leprosy. The anemia of ankylos-tomiasis is almost invariable among the poor and is spread by eating with soiled fingers. Scarlet fever is unknown. Pneumonia is seldom fatal. Malaria is rare. Yellow fever has not appeared for ten years. Diphtheria occurs, but generally in a mild form, and smallpox has been prevalent in the past. All Americans sometime contract dengue, from which they soon recover. What the people need is instruction in sanitation and better nutrition. They are honest, industrious, intelligent, law-abiding and proud of their American citizenship.

7. **Cholelithiasis.**—Deaver reviews the subject generally, and urges that the best possible time for the patient to be referred to the surgeon is when the stones are still in the bladder, that the severity of the disease increases and the case is less promising after the stone has passed into the duct and that there is practically no mortality from removal of stones from the bladder, but common duct operations are serious. He advises his medical colleagues to witness gall bladder surgery and familiarize themselves with the conditions.

8.—See abstract in THE JOURNAL of December 6, p. 1476.

10. **Formaldehyd in Tuberculosis.**—Shalleross describes a home-made inhaler by using a perforated cork and a pint salt mouth bottle, two glass tubes being passed through the perforations. To one of these is attached a rubber tube at the end of which is an inhaler made by cutting off the end of a rubber bulb. The tube is partially filled with a roll of mosquito wire gauze covered with cheese cloth, coiled up in the tube, which absorbs the formaldehyd mixture. The mixture which has given most general satisfaction consists of equal parts of 40 per cent. commercial formaldehyd and 95 per cent. alcohol. Other agents may be added as desired. About 12 drams is sufficient to moisten the gauze and leave an excess which will last for two or three months without renewing. He sums up his conclusions as follows:

As a therapeutic adjunct in the treatment of pulmonary tuberculosis formaldehyd possesses certain distinct advantages.

It is a gaseous substance, having about the same specific gravity as air with which it readily diffuses, and is soluble in water.

It is the most powerful chemical disinfectant known and the nearest approach to a pulmonary antiseptic we have.

It is a stimulant non-toxic and does not irritate the respiratory tract when administered in the proper manner.

It lessens the absorption of toxins, reduces pyrexia, relieves nervous symptoms and night-sweats and sharpens the appetite.

Cough is lessened by its property to liquefy and render more mucous the secretions, and by relieving the irritation of the pharynx and larynx.

12. **Cancer of the Rectum.**—Pennington describes a special form of x-ray tube and shield which he has employed for cancer of the rectum to obviate the difficulties usually met.

13. **Adenoiditis in Children.**—Swain describes a condition in children which he considers due to inflammation of the tonsils, especially the third tonsil, namely, common febrile attacks sometimes becoming more extended and producing serious constitutional conditions. He believes that these tissues are normal in the body, but should be removed when overgrown for mechanical reasons and on account of the possibility of their producing mischief. He does not authorize general annihilation of lymphoid tissue; but the earlier the third tonsil is removed, other things being equal, the better. It should be taken away as soon as it is known to be the cause of any trouble. For treatment he advises sprays with Seiler's tablet solution with suprarenal, and powdered boric acid in the nose as probably accomplishing a great deal in most cases. Peroxid of hydrogen should be used only in weak solution. Its prolonged use is not to be recommended, and for the constitutional conditions we should depend mainly on local cleansing, reduction of the inflammation in the throat with change of air, good food and nutrition.

15. **Adrenalin in Urethral Work.**—Gans reports cases of posterior urethrotomy treated with adrenalin with good results, in spite of the obstinate character toward other drugs. He thinks the usefulness of this drug is limited to the same indications as for mucous membranes in other localities. It needs watching for untoward action.

17. **X-Rays in Uterine Cancer.**—Cleaves details a case of cervical uterine cancer which was treated with the Roentgen ray with apparent good results.

18. **Pulmonary Syphilis.**—The probability of syphilitic disease of the lung being mistaken for tuberculosis is noticed by Berg, who reports a case which recovered under the iodids. He discusses the pathology, symptoms, etc. It may resemble tuberculosis or subacute or chronic pneumonia. It may exist in the form of gummata with more or less extensive bands, and may produce abscess cavities. He has not seen the last two classes, though he has seen several cases simulating tuberculosis or pneumonia. Its progress is really much slower than the pulmonary disease, but otherwise the symptoms are often very similar. The treatment, of course, is specific.

19. **Pancreatic Disease.**—Blodgett describes three phases. 1. Extension from disease elsewhere; 2, part of a general process; 3, pancreatic disease *per se*. Each is illustrated by cases. He thinks that pancreatic disorder may be frequently a cause of indigestion and other disorders that are not thus ascribed.

22. **Infantile Paralysis.**—Painter describes an epidemic at Gloucester, Mass., in the summer of 1900. There were 23 males and 9 females, aged from 13 months to 10 years. No case recovered entirely, but only one died, though this one was not included among the 38 reported. He does not venture to explain the cause of the epidemic, but considers several organisms capable of producing the symptom-complex. The majority of cases occurred after a period of extreme heat, and in some cases from a sudden or sharp drop from abnormally high temperature and others followed bathing in the sea.

24. **Leucoplakia.**—Cobb's article is a general review, in which he seems to hold the smoking habit to be the leading etiologic factor. Syphilis seems to have been present in some of his cases, but was not so prominent as is claimed by Fournier.

25. Ureteral Suturing.—After reporting a case which Cabot operated on by the end-to-end method he describes the various methods. He thinks the transverse end-to-end method which has been done twelve times with two deaths necessitates the sacrifice of less ureter than any other one, but it has some technical difficulties and is more likely to leakage. The oblique end-to-end has about the same limitations, though it requires the sacrifice of a small portion of the ureter. The end-in-side method of Van Hook is only applicable in cases where plenty of slack is to be had and might be impossible, but is probably as easy as any of the methods and a good deal less likely to leak. The end-in-end method is applicable where a moderate amount of ureter up to an inch can be utilized and is quite as easy as the end-in-side method and seems to have a larger range of application, requiring less sacrifice of tissue. He concludes that attempts to suture the divided ureter should always be made before it is implanted in the vagina, rectum or skin or the formerly popular operation of nephrectomy is resorted to.

26. Malignant Disease of the Gall Bladder.—Mayo finds that gallstones are almost constantly present in primary malignant disease of the gall bladder and rarely in secondary; that the relative proportion of gallstones and malignant disease of the gall bladder in women and men is practically identical, and the pathologic lesions are best explainable on the theory of the etiologic relation of gallstones to malignant disease. He reports cases which are of interest in this connection.

27. Cholelithiasis.—Deaver reviews the operations for cholelithiasis, advocating early surgical treatment. He describes the different operations and their adaptations to different conditions. If the gall bladder is but slightly diseased, cholecystotomy may be sufficient; if suppurative cholecystitis exists, cholecystotomy with drainage is required. Stone in the ducts should call for special operation accordingly. Cholecystectomy is frequently difficult, and he apparently does not advocate its general employment.

29. Ulcerative Endocarditis.—Manges reports his experience with Credé's intravenous injection of collargol in septic endocarditis, reporting two cases with recovery. He says such results are sufficiently striking to warrant further trial. He also reports two cases of ulcerative endocarditis with less good effect, the patients being unimproved.

30. Asphyxia in Anesthesia.—Bennett points out that this condition may be due to the exclusion of oxygen by paralysis of the respiratory center, by the production of some unknown condition producing cyanosis as in some chloroform cases, or by the mechanical obstruction of respiration. He notices the signs, circulatory and muscular, and suggests the use of oxygen among other remedies.

32. Epilepsy in the Young.—The causes of epilepsy in infants are reviewed at length by Jacobi, who thinks it is impossible to estimate the frequency of the condition. He mentions as possible causes, dissipation and drug habits of the parents, syphilis, intermarriage, etc., and lays considerable importance to hypertrophy of the brain and the lack of proper relation between it and the cranium and often from too early and irregular ossification. Intrauterine influences are serious in this connection. A frequent cause of epilepsy is asphyxia of the new-born and intracranial hemorrhages not connected with asphyxia which are very frequent. The frequency of convulsions of infancy and childhood is another danger, and he notices some of the causes of these, irritations, as from dentition, or phimosis, rachitis, etc. He objects to the extreme methods to prevent masturbation, and thinks they can do but little good.

35. Physiology of Vision.—Gould reviews the causes of deterioration of the function of vision by abnormal light stimulus, etc., including among them shifting of shadows of retinal arteries and veins, the reflections from the blood-corpuscles of the capillaries of the retina, or phosphores, muscæ volitantes, to the extension of the retinal pigment, iris-pigmentation, alteration of contraction and dilatation of the pupil under stimuli, the natural pigmentation of the skin, the shading function of the eyelash, the action of winking, binocular vision breaking up the continuance of the stimulus of the retina, the

movements of the eye, head and body aiding, the shading influence of the eyebrows, all of which are evidence of the difficulties met and conquered by Nature in the evolution of the eye. He thinks that when this important law of retinal fatigue and recuperation is recognized almost all of our practical and esthetic laws will be revolutionized.

1. **Acute Manifestations of Chronic Disease.**—Bruce calls attention to the fact that what we commonly call acute disease is in many instances nothing else than an acute exacerbation of a chronic condition. He insists on the importance of recognizing the primary cause and the utility of the acute attacks sometimes in revealing it. We may forget the chronic element or be blinded to it by the circumstances attendant on acute illness, especially if the latter take the forms of substantive disease, so-called. Pleurisy is a disorder which he considers the one of all others most likely to lead us astray in this respect. Its association with chronic abdominal disease, as well as with thoracic troubles, must be kept in mind. Immediate prognosis like the immediate treatment of acute illness can not be expected to be successful if the chronic underlying condition is not recognized. What we should do in most of these cases is not to try to simply prevent recurrence of similar attacks, but to bring about and arrest the primary disease in its course while it is still of comparatively slight degree and in safe location.

3. **Colon Catarrh.**—The primary symptoms of this condition are considered by Wilson to be first, excessive mucous secretion; second, excessive irritability of the muscular coats, causing them to harden and become palpable; third, constipation, due probably both to altered secretion and altered motility; fourth, pain, often colicky, and tenderness; fifth, nervous phenomena, especially mental depression and sometimes true neurasthenia. It is the symptoms of acute, subacute and chronic catarrh that he wishes specially to call attention to, and he gives the details in regard to them which we can not reproduce here. He notes as regards the question of the diagnosis of typhlitis from appendicitis, which is rather a large question, that the condition of localized tenderness after the acute symptoms have passed off, is more in favor of appendicitis. If the cases are recognized early enough and are properly treated by diet and medicine the prognosis as to recovery is satisfactory. In some chronic cases the best one can do is to keep the symptoms in check. Some cases seem inveterate. We must remember the rheumatic element of colitis. Salicylates are mentioned. We must regard the irritability of the colon, especially in the matter of diet and avoid any vegetables containing much woody fiber, seeds, skins, etc., as well as all indigestible solids. The nervous symptoms must be treated by attention to hygiene, climate and social treatment as well as medicine.

5 and 6. **Pneumonia.**—The third lecture by Washbourn deals with the bactericidal action of the various sera, the method of recognizing the pneumococci in the lesions, their existence under other circumstances in health, their localization in disease, and the anatomy of the lung.

7. **Cardiac Pain.**—The diagnosis of angina pectoris is taken up by Morison in his fourth lecture. It includes not only the determination of the varieties of that disease from one another, but of the syndrome of angina from other conditions which resemble it, but affect other structures. We must keep three

different points in mind: 1. The situation of the pain; 2, character of consequences of the pain; 3, the fact whether respiration is affected by the pain. In true angina involving only the heart, respiration is really unaffected. The degree of pain can not be taken as a measure of its seriousness. Some of the false anginas seem to cause more suffering than the more serious ones. The criteria of the danger of the case are not obtained except by a comprehensive view of the whole circumstances. Sex is an important factor, however, and the dangerous forms are invariably more common in man than woman. Age is also a factor, and if we exclude the consequences of syphilis and general debauchery it is rare. After 60 or 70 years, to pronounce a man absolutely sound and prescribe violent exercise would be imprudent, but given a comparatively young subject with normal radial arteries free from heart affection and without a history of syphilis, one can generally be justified in looking after the transient cause of the pain and in expecting disappearance of the effects. In a person over 50, on the other hand, anginal symptoms suggest the serious form. The value of x-rays in the diagnosis is mentioned at length and the prognosis of the true form is generally bad. Only care as to the habits, diet, etc., will in any measure protect one who has survived one attack. With angina *sine dolore*, being generally due to muscle failure, the prognosis is gravest, and the cardiac muscle is nearer the termination of its vital possibilities. He mentions as regards treatment the necessity of anyone wishing to reach 70 years being careful in his diet and habits after the age of 50. The Nauheim baths are mentioned as possibly safe in some cases, but they are out of consideration in anything but the mildest ones. The nitrites seem to be the principal drugs in the treatment of the paroxysms and for producing and keeping an equable blood pressure certain drugs must be used. He speaks against the use of tobacco in this condition, but believes in the use of mild mercurials as aiding in keeping up the proper condition of the circulation.

11. **Katjang Idjo, a Remedy for Beri-Beri.**—This communication from the insane asylum of Buitenzorg, Java, states that the berry or pea of the *Phaseolus radiatus*, a common plant, has proved effectual in the treatment of beri-beri. It was thoroughly tested on the 250 to 300 inmates of the asylum, and displayed a marked prophylactic action when an average of 150 gm. of the peas were eaten regularly every day. No injurious effects of any kind were noted even after prolonged use. It also proved a good remedy against the infection itself, but had no influence on the sequelæ. The edema rapidly subsided under its influence and likewise the paresis in the acute cases, which is liable to persist for months. Its influence was particularly beneficial in the severer forms of the disease. The asylum has long been infested with beri-beri, but not a single case has occurred in the pavilion in which the inmates take regularly 150 gm. of the peas in their daily ration. The natives make great use of these peas both in their own food and for poultry. Burg states that the plant was recommended as a remedy for beri-beri in the seventeenth century.

19. **Intratracheal Injections of Mercury in Syphilis.**—Carnot suggests that great benefit might be derived from inhalation of mercurial preparations in a closed chamber. This would ensure absorption both by the respiratory apparatus and the skin. The mucosa of the respiratory passages is remarkably tolerant of mercury, and the absorption in the trachea is so rapid that 2 liters of fluid can be injected into the trachea of a horse in the course of an hour without inconvenience, and 40 c.c. per kilogram an hour in a rabbit, which is equivalent to 2.5 liters for a man. The rapidity of absorption by intratracheal injection is comparable to that from intravenous injection, but has none of its disadvantages. Levi of Pisa has demonstrated that substances can be injected into the trachea, without any reaction, which are caustic for the digestive tract. Botey found that the injection of .5 c.c. of a 5 per cent. solution of nitrate of silver was tolerated by the trachea far better than by the stomach. Injection into the trachea of a 1 per cent. solution of sublimate or of .4 per cent. solution of gray oil was well tolerated in Carnot's experience and never caused prolonged coughing, râles, dyspnea, and nor any unusual cardiac

action. If a little was swallowed the subjects complained of prolonged pain in the stomach, while the same solutions in the trachea caused at most a slight tickling or sometimes a little hoarseness. He has found a 1 per 1000 solution of sublimate the most convenient for the purpose, injecting daily about 5 to 10 c.c. The results were extremely favorable in the 30 cases thus treated. The impression was derived that the action of the mercury was more prompt by this than by other methods of administration. In case the technic is defective and the fluid is swallowed, no harm is done. The procedure is very simple and does not betray the nature of the affection under treatment.

29. **Calcium in Epilepsy.**—Audenino published last year the result of researches which demonstrated that the proportion of earthy phosphates eliminated was much below normal in the cases of moral insanity examined. The present communication describes similar researches on 19 epileptics, and an almost constant subnormal proportion of the earthy phosphates was similarly demonstrated in 88 out of 91 examinations of urine and feces. This defective elimination did not parallel the general diminution of the chemical processes observed in epileptics. Nine of the subjects were given calcium in various forms, and in 7 there was slight increase of the earthy phosphates in the urine, and a large increase in the feces after administration of 2 to 8 gm. of calcium bromid or .5 to 2 gm. of the carbonate, lactophosphate or glycerophosphate, or lime water. These were all old, severe cases. In the other two patients the epilepsy was severe, but of more recent date. The calcium was eliminated principally through the urine and but little was found in the feces. A marked improvement followed the administration of the calcium, and one patient was dismissed as cured, there having been no seizures for four months. The particulars of the elimination and absorption are tabulated in typical cases.

30. **Laws of Chemical Physics Applied to Clinical Research.**—Ceconi demonstrates that the laws governing solutions in general, and especially electrolytic fluids, apply to the organic fluids, and to the serum in particular. He proclaims that they should be studied from this point of view as a means of clinical diagnosis. The serum behaves in regard to the osmotic pressure the same as a pure aqueous saline solution. The proteins in it have no osmotic pressure, or so little that it can be disregarded. As Bladgen's law does not apply to saline solutions, which obey the van t'Hoff-Arrhenius law, the study of the organic fluids should always include the application of the latter. The serum also contains both electrolytic and non-electrolytic substances, and obeys the laws regulating such fluids.

37. **"Gargling" the Posterior Urethra.**—Binaghi applies this term to the injection of a small amount of an antiseptic solution; the tip of the catheter in the posterior urethra and the fluid ejected with force, "à coups de piston," a little at a time, until all has been injected. By this means the posterior urethra is dilated and "gargled," and his experience with urethrostatis treated in this way has been exceptionally favorable. He uses a solution of boric acid and repeats the maneuver several times at a sitting, following it with an antiseptic lavage with a 1 per 1000 solution of silver nitrate, using extreme care to prevent pain or spasm. He describes seven cases in detail to illustrate the merits of this method.

42. **Health Resorts for Heart Disease.**—Licata asks why we can not send patients with heart disease to suitable watering places with the same confidence with which we send a tuberculous patient to a sanatorium. The treatment of heart disease is pre-eminently with hygiene, dietetics, thermal baths and kinsiotherapy, and yet very few watering places, he says, study to scientifically apply the measures most beneficial for heart disease.

43. **Nerves in Etiology of Neoplasms.**—Campana concludes from the research he describes that the nerves play an important part in the origin of neoplasms.

44. **Influence of Mineral Waters on Elimination of Bile.**—A patient with a biliary fistula ingested equal amounts of the popular thermal waters with an interval of rest between

each. The amount of bile eliminated, the specific gravity and the proportion of fixed substances was recorded for each period. There was very little increase of bile after ingestion of Carlsbad salts or water, but the amount rose from 100 to 142 c.c., when the waters of an Italian spring (Montecatini) were taken. This effect was constant in four repetitions with these waters, while under repeated tests with Carlsbad waters or salts the amount never rose above 107, and was even 85 on one day.

48. **Endovenous Injections of Oxygen in Man.**—Mariani's experiences were mentioned in THE JOURNAL of August 23, p. 460.

49. **Experimental Paraffin and Agar Prothesis.**—Paraffin, with a melting point at 41 and 50 C., and a 4 per cent. solution of agar were injected into rabbits to test their suitability for subcutaneous prothesis. The results were unfavorable in every instance.

50. **Sensibility of Stomach from the Semeiotic Point of View.**—Supino remarks that the trained hand is more reliable than any apparatus that has yet been devised for testing the sensibility of the stomach. He confirms the assumption that hyperchlorhydria is the rule in both alcoholism and chlorosis. He reviews and explains the findings in respect to the sensibility in various conditions.

51. **Mechanics of Tremor.**—Boeri shows that the oscillations of tremor obey the laws that govern the swinging of a pendulum. The contraction of the muscles takes the place of gravity. He calls attention to the constancy of the rhythm, and to the fact that the number of oscillations is never more than 10 or 12 to the second, or at the utmost 14. This limit of the oscillations is the same as for voluntary movements. He was never able to voluntarily reproduce a tremor with a more rapid rhythm than this.

53. **Antiplague Vaccination by the Mouth.**—Vincenzo administered by the mouth to fasting guinea-pigs .6 to .3 gm. of the active substance of Haffkine's antiplague vaccine in a single dose. The results indicated that a considerable degree of immunization was realized, but the animals that had received the larger doses died with symptoms of gastroenteritis. Later experiences with smaller, repeated doses of the vaccine by the mouth are proving still more encouraging.

54. **Actinomyces Granuloma.**—Secchi points out the resemblance between the mode of development of a granuloma caused by actinomyces and a tubercular or syphilitic gummatous formation. It resembles these lesions also in other respects, by the rapid necrosis, its mode of spreading, etc. The actinomyces has both a pyogenic and neoplastic action, but the former can not be called actual suppuration. The pyogenic virulence of the microbes is evidently of brief duration.

56. **Hirschsprung's Disease and Idiopathic Megacolon.**—Tarozzi describes an extreme case of the latter in a man of 50. The loop of the colon occupied nearly the entire front of the abdomen, the distance across measuring 30 cm., 10 for the ascending and 14 for the descending loop, with 6 for the interposed mesocolon. The intestine measured 40 cm. in circumference at the largest part. He presents arguments to establish that this idiopathic dilation is an acquired condition in adult life, while Hirschsprung's disease is a congenital affection in children.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department of the U. S. Army under orders from the Adjutant-General's Office, Washington, D. C., from Dec. 1 to 6, 1902:

Ames, Elvin W., captain, U. S. V., now serving in the Division of the Philippines, is honorably discharged by the Secretary of War from the service of the United States, his services being no longer required.

Beatty, Walter K., by direction of the Secretary of War, leave of absence for 25 days is granted.

Boyd, Robert, captain and asst.-surgeon, U. S. V., under instructions from the President, Paragraph 16, Special Orders, No. 276, Nov. 24, 1902, relative to Captain Boyd, is revoked by the Secretary of War.

Boyd, Robert, captain and asst.-surgeon, U. S. V., is honorably discharged by the Secretary of War from the service of the United States, to take effect Dec. 31, 1902, his services being no longer required. He will then proceed to his home.

Under instructions from the President, the following named officers, now at San Francisco, are honorably discharged by the Secretary of War from the service of the United States, to take effect Dec. 31, 1902, their services being no longer required: Major Joseph N. Henry, surgeon, U. S. V.; Major George B. Lawrason, surgeon, U. S. V.; Major Charles B. Nichols, surgeon, U. S. V.; Captain Fred F. Sprague, asst.-surgeon, U. S. V.; Captain Arthur D. Prentice, asst.-surgeon, U. S. V.; Captain Arthur Jordan, asst.-surgeon, U. S. V.; Captain Hyman M. Cohen, asst.-surgeon, U. S. V.; Captain Henry W. Eliot, asst.-surgeon, U. S. V.; Captain William W. Calhoun, asst.-surgeon, U. S. V.; Captain Reuben M. Bonar, asst.-surgeon, U. S. V.; Captain Percy L. Jones, asst.-surgeon, U. S. V.; Captain Fred W. Palmer, asst.-surgeon, U. S. V.; Captain Paul Mazzuri, asst.-surgeon, U. S. V.; Captain Thurston Smith, asst.-surgeon, U. S. V.

De Shon, George, major and surgeon, U. S. V., captain and asst.-surgeon, U. S. A., is honorably discharged by the Secretary of War from the service of the United States as major and surgeon, U. S. V., only, to take effect Feb. 1, 1903, his services being no longer required.

Enders, Robert M., captain and asst.-surgeon, U. S. V., as Captain Ames, above, to take effect Dec. 8, 1902.

Gibson, Edward T., captain and asst.-surgeon, U. S. V., as Captain Enders, above.

Strong, Richard P., first lieutenant, U. S. A., the resignation of his commission as an officer of the Army has been accepted by the President, to take effect Dec. 5, 1902.

Van Poole, Gideon McD., first lieutenant, and asst.-surgeon, U. S. A., is granted leave of absence, to take effect on or about Dec. 4, 1902.

Under instructions from the President, the following named officers are honorably discharged by the Secretary of War from the service of the United States, to take effect Feb. 1, 1903, their services being no longer required:

Major and Surgeons, U. S. V.—Arlington Pond, Henry D. Thomson, Robert H. Zauner, Walter Whitney, Thomas C. Chalmers, Seaton Norman, Shadworth O. Beasley, Frederick A. Washburn, Jr., George P. Peed, William D. Bell, Lawrence C. Carr, Abram L. Haines, Simon J. Fraser, Howard A. Grube, Robert Burns, Joseph C. Reifsnnyder, Lewis T. Griffith, Roger P. Ames, William D. Shelby.

Also Captains and Assistant Surgeons, U. S. V.—Clark I. Wertenbaker, James S. Kennedy, Guy G. Bailey, Edward F. Horr, Elmer S. Tenney, Samuel D. Huntington, James F. Presnell, Frederick H. Sparrenberger, Harold W. Cowper, Henry A. Littlefield (U. S. A.), Gerry S. Driver, Justus M. Wheate (U. S. A.), Ernest H. Wheeler, George R. Plummer, William R. Van Tuyl, William F. James, Frank W. Dudley, George S. Wallace, Timothy F. Goulding, Charles F. de Mey, Rene Vandam, Fred M. Barney, William G. Miller, Edwin C. Shattuck, Albert L. Miller (U. S. A.), Charles G. Elcher, Gilbert I. Cullen, Raymond E. Whelan, Cyrus D. Lloyd, William E. McPherson, Thomas H. Lander, Charles A. Cattermole, John S. Hill, Percival S. Rossiter, Frank DuBois, Samuel K. Carson, Najeeb M. Saleeby, Herman Schlageter, Alva S. Pinto, William R. Davis, Thomas C. Lougino, Charles W. Hack, Charles R. Gill, Francis J. Pursell, William T. Tanner, James G. McKay, William B. Summerall, Thomas K. Mulhaus, Frederick A. W. Conn, Luther P. Howell, Leonard K. Graves, Samuel T. Weirick, Michael E. Hughes, H. Brookman Wilkinson, Abraham D. Williams, John Gilbert, Robert E. Caldwell, George H. Calkins, W. Turner Wootton, Michael A. Rebert, Henry DuR. Phelan, Edwin M. Trook, William P. Baker, Luke B. Peck, Thomas R. Marshall, William C. LeCompte, Herbert Gunn, Waldemar A. Christensen, Edward A. Romig, Herbert M. McConathy, James B. Pascoe, Joseph L. Sanford, Thomas S. Lowe, William A. McVean, Francis J. Bailey, John P. Kelly.

Navy Changes.

Changes in the Medical Corps of the Navy, for the week ending December 13:

Medical Director F. M. Gunnell, retired, ordered to the Bureau of Medicine and Surgery.

P. A. Surgeon E. O. Huntington, detached from treatment at the Naval Hospital, New York, and ordered to duty at the Navy Yard, New York.

P. A. Surgeon W. H. Bucher, ordered to duty at the Naval Hospital, Norfolk, Va.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Dec. 4, 1902:

Surgeon G. W. Stoner, 7 days' leave of absence under Paragraph 179, of the regulations.

Surgeon H. R. Carter, detailed to represent the service at meeting of American Public Health Association at New Orleans, December 8-13.

Surgeon Eugene Wasdin, granted leave of absence for 21 days from December 15.

Surgeon G. M. Magruder, leave of absence for 12 days from November 17, 1902, granted by Bureau letter of Nov. 6, 1902, amended so that said leave shall be for 8 days.

Surgeon J. O. Cobb, on expiration of leave of absence, relieved from duty at Portland, Ore., and directed to proceed to Los Angeles, and assume command of the service at that port.

P. A. Surgeon C. P. Wertenbaker, detailed to represent the service at meeting of American Public Health Association at New Orleans, December 8-13.

P. A. Surgeon J. A. Nydegger, granted leave of absence for 6 days from December 8.

P. A. Surgeon H. W. Wickes, detailed as inspector of unserviceable property at Cleveland, Ohio.

P. A. Surgeon H. S. Mathewson, granted leave of absence for 7 days.

Asst.-Surgeon W. C. Billings, assigned to duty in the office of the U. S. Commissioner of Immigration at St. John, N. B.

Asst.-Surgeon C. W. Wille, to proceed to Baltimore, for temporary duty.

Asst.-Surgeon B. J. Lloyd, granted leave of absence for 3 days.

Asst.-Surgeon L. P. H. Bahrenburg, granted leave of absence for 7 days from November 25.

Asst.-Surgeon W. C. Rucker, Bureau order of Nov. 26, 1902, directing him to proceed to the Immigration Depot, New York, for temporary duty, revoked; and directed to proceed to Boston, and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon W. K. Ward, relieved from duty at Boston, and directed to proceed to Reedy Island Quarantine and report to medical officer in command for duty and assignment to quarters.

A. A. Surgeon C. W. Bailey, granted leave of absence for 7 days from December 7, 1902.

A. A. Surgeon H. J. Hamilton, granted leave of absence for 2 days.

BOARDS CONVENED.

Board convened at Washington, D. C., Dec. 3, 1902, for the physical examination of an officer of the Revenue Cutter Service. Detail for the Board: Asst.-Surgeon J. F. Anderson, chairman; Asst.-Surgeon Edward Francis, recorder.

Board convened at Washington, D. C., Dec. 4, 1902, to revise the uniform regulations of the service. Detail for the Board: Assistant Surgeon-General G. T. Vaughan, chairman; Surgeon H. W. Sawtelle; Asst.-Surgeon B. S. Warren, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Dec. 12, 1902:

SMALLPOX—UNITED STATES.

California: Fresno, Nov. 1-30, 2 cases.
Colorado: Denver, Nov. 22-29, 1 case.
Florida: Jacksonville, Nov. 22-Dec. 6, 3 cases; Pensacola, Nov. 22-Dec. 6, 5 cases.
Georgia: Atlanta, Nov. 27-Dec. 3, 1 case.
Illinois: Chicago, Nov. 29-Dec. 6, 1 case; Evanston, Oct. 1-Nov. 30, 65 cases.
Indiana: Evansville, Nov. 29-Dec. 6, 1 case; Hammond, Nov. 23-30, 34 cases; Indianapolis, Nov. 29-Dec. 6, 8 cases, 1 death; Muncie, Nov. 1-30, 2 cases.
Iowa: Ottumwa, Nov. 1-22, 22 cases.
Kansas: Wichita, Nov. 15-29, 2 cases.
Maine: Biddeford, Nov. 29-Dec. 6, 11 cases.
Massachusetts: Nov. 29-Dec. 6, Boston, 23 cases, 7 deaths; Chicopee, 1 case; Everett, 2 cases; Lawrence, 1 case; Taunton, 1 case.
Michigan: Grand Rapids, Nov. 29-Dec. 6, 5 cases.
Missouri: St. Joseph, Nov. 29-Dec. 6, 1 case.
Nebraska: Omaha, Sept. 1-Dec. 6, 9 cases.
New Hampshire: Nashua, Nov. 29-Dec. 6, 21 cases.
New Jersey: Jersey City, Nov. 30-Dec. 7, 1 case.
New York: Nov. 29-Dec. 6, Binghamton, 1 case; Buffalo, 2 cases; New York, 1 case.
North Carolina: Charlotte, Nov. 1-30, 89 cases, 13 deaths.
Ohio: Cincinnati, Nov. 28-Dec. 5, 3 cases; Cleveland, Nov. 29-Dec. 6, 11 cases, 1 death; Toledo, Nov. 22-Dec. 6, 9 cases; Warren, Nov. 29-Dec. 6, 1 case; Zanesville, Nov. 1-30, 2 cases.
Pennsylvania: Nov. 29-Dec. 6, Altoona, 3 cases; Erie, 2 cases; McKeesport, 1 case, 1 death; Philadelphia, 6 cases, 1 death; Pittsburg, 36 cases, 6 deaths.
South Carolina: Charleston, Nov. 29-Dec. 6, 2 cases.
Tennessee: Chattanooga, Nov. 1-30, 1 death.
Texas: San Antonio, Nov. 1-30, 1 case.
Utah: Salt Lake City, Nov. 22-Dec. 6, 3 cases, imported.
Wisconsin: Green Bay, Nov. 30-Dec. 7, 1 case; Milwaukee, Nov. 29-Dec. 6, 4 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Nov. 8-22, 38 cases.
Belgium: Antwerp, Nov. 8-22, 4 cases, 1 death.
France: Marseilles, Oct. 1-31, 25 deaths; Paris, Nov. 15-22, 1 death; Rheims, Nov. 17-23, 1 case, 1 death.
Gibraltar: Nov. 2-16, 3 cases.
Greece: Athens, Nov. 15-22, 1 case.
Great Britain: Bradford, Nov. 1-15, 6 cases; Dundee, Nov. 15-22, 3 cases; Leeds, Nov. 15-22, 17 cases, 1 death; Liverpool, Nov. 15-22, 58 cases, 1 death; London, Nov. 8-22, 8 cases.
India: Bombay, Nov. 4-11, 4 cases, 4 deaths.
Italy: Palermo, Nov. 8-15, 3 cases.
Mexico: Nogales, Nov. 8-29, 15 cases.
Russia: Moscow, Nov. 1-8, 3 cases; Odessa, Nov. 8-15, 4 cases; Rifa, Sept. 1-30, 16 deaths; St. Petersburg, Nov. 1-15, 10 cases, 2 deaths; Warsaw, Oct. 25-Nov. 1, 2 deaths.

YELLOW FEVER.

Costa Rica: Port Limon, Nov. 22-29, 2 cases, 1 death.
Dutch West Indies: Buen Ayre, Nov. 15, 1 death on Dutch schooner trader.
Ecuador: Guayaquil, Nov. 15-22, 1 death.
Mexico: Tampico, Nov. 22-29, 23 deaths; Vera Cruz, Nov. 22-29, 14 cases, 2 deaths.

CHOLERA.

Dutch Indies: Java, Batavia, Oct. 4-25, 83 cases, 76 deaths.
India: Bombay, Oct. 29-Nov. 4, 1 death; Calcutta, Oct. 25-Nov. 8, 54 deaths.
Japan: Nagasaki, Nov. 1-10, 1 case.

PLAGUE—UNITED STATES.

California: San Francisco, Nov. 27, 1 case, 1 death.

PLAGUE—FOREIGN.

India: Bombay, Oct. 29-Nov. 11, 238 deaths; Calcutta, Oct. 25-Nov. 8, 18 deaths; Karachi, Oct. 26-Nov. 9, 31 cases, 24 deaths.
Japan: Yokohama, Nov. 1-8, 1 death.

GENERAL INDEX.

Use of the index will be facilitated by bearing in mind that subjects are frequently given under two or more headings, e. g., brain, cerebral, tumors, etc.; heart and cardiac; cirrhosis, liver and hepatic; child, children and infant; gland, thyroid, etc. Often, too, writers treat of the eye, ear, nose and throat under one head, etc., and the titles do not always permit of indexing under the several headings. The "General Index" contains only titles of articles, subjects of editorials, society proceedings, abstracts, and miscellaneous matter appearing in THE JOURNAL; the titles of editorials, book notices, deaths, societies, marriages, Association news, medical organization, and state boards of registration are indexed and arranged under their separate headings in the "Index of Departments," instead of in the body of the "General Index." The "General Index" contains the subjects of articles in other journals which have been abstracted in THE JOURNAL. The titles and authors of all other articles from other journals are under the "Current Medical Literature" Index.

MEDICOLEGAL

- Accident, communication to am-
 bulance surgeon as to, 45
 Admission, liability of refusals of,
 218
 Anatomic science, law to promote,
 District of Columbia, 932
 Appropriation for services, phy-
 sician must show prior, 1413
 Autopsies in insane hospitals,
 Massachusetts, 1208
 Board of health, council must
 act on nominations for, 218
 Cemetery, state board of health
 and location of, 1614
 Cocain, restricting selling of, in
 Ohio, 860
 sale of, in Iowa, 717
 Commitment to insane hospital,
 requirements for, 606
 Consumption, classification and
 reporting of, 331
 Consumptives, new sanatorium
 for, Massachusetts, 1209
 Contagious diseases, provisions
 for, New Jersey, 800
 Contract for compensation, en-
 forcible, 506
 Criminal liability of physician,
 1277

- Criminal responsibility, test of, 331
- Death, cause of, copy of record of certificate of, 276
- Delirium tremens, 1546
- Dentists, itinerant doctors' statutes and, 1545
- Disease, liability for hastening development of, 1614
- Doctor, use of title of, 1278
- Employment of physician by bookkeeper or manager, 218
- Evidence, 1003
- Expense of nurse and ward in hospital recoverable, 276
- Expert, competency of, 1136
- evidence, failure to introduce, 586
- witness, cross examination of, 334
- Extreme cruelty, physical violence not necessary to, 505
- Eyes, \$12,500 for injury to, 1614
- Failure to appear before board, 276
- to introduce x-ray or expert evidence, 586
- Fracture of femur, \$3,000 for, 1413
- Health officer, salary only recoverable by, 1481
- Hospitals, relief of benevolent and charitable, 859
- Infected persons, prohibition of, in Virginia, 932
- Injured person, duty of, in employment of physician, 1068
- persons, mistakes in treatment of, 45

 Epididymitis, treatment of, 1412
 Epilepsy, 44, 275
 Brysipelas, 505, 651
 Expectorants in bronchitis, 1544
 Febrile and wasting diseases, nutritive lemonade for, 331
 Feeding young children, general rules for, 159
 First aid in injuries to the eye from lime, 446
 Freckles, 102
 Gastralgia in children, 1343
 Gastric lavage in infants, 1277
 Gonorrhea, diet in, 1614
 picric acid in treatment of, 1003
 rectal, 931
 Gout, 1545
 Hemiparesis, 1544
 Hemoptysis, 1544
 Hemorrhage from the nose or throat, 1342
 Hemorrhages in infectious diseases, 585
 Heroin in asthma, 1276
 Herpes zoster, 1479
 Hot and cold water in eye diseases, 1614
 Hydrotherapy in chlorosis and secondary anemia, 1613
 Hyperchloridia, 102
 Impetigo contagiosa, 1207
 Inhalation in tuberculosis, 1003
 Iodoform in pulmonary tuberculosis, 505
 Keratitis phlyctenular, 1067
 La grippe, 931, 1544
 Laryngitis, tubercular, 1412
 Lemonade, nutritive, for febrile and wasting diseases, 331
 Lupus, caustic treatment of, 650
 Lymphatic glands, enlarged, 102
 Malaria, 1208
 Methyl blue in cancer, 1208
 Migraine, 159
 Myocarditis, 1008
 Nephritis, acute, 1480
 Neuralgia, 585
 benign facial, 276
 Normal saline solution, 1343
 Oleum ricini in typhoid, 275
 Orthoform as local anesthetic in laryngeal tuberculosis, 505
 Otitis media, chronic, 275
 Ozone in pertussis, 1208
 Pemphigus, 393
 Pertussis, 931
 ozone in, 1208
 Pharyngitis, granular, 392
 Phosphaturia, dyspepsia and, 445
 Picric acid in treatment of gonorrhea, 1003
 Pneumonia, 1343
 Pregnancy, continuous vomiting of, 585
 Proctitis, 393
 Prostatic disease, 585
 Pruritus, 159, 793
 vulvar, 651
 Pytalism, mercurial, 275
 Rheumatism, 588
 Rhinitis, atrophic, 1002
 Salol in cystitis, 1544
 Rubefacient cataplasms, a, 1207
 Salicylates, use of, in children, 931
 Scabies, 1134
 Scarlet fever, turpentine in, 1480
 Sciatica, 1068
 Seasickness, 393
 Solutions for douches, 1003
 Spermatorrhea, 217
 Stomach, certain disorders of, 330
 dilatation of, 1545
 Sweating of feet, 331
 Thiogenol, 102
 Tincture of myrrh in diphtheria, 650
 Tonsillitis, acute, 446
 Tuberculosis, diet in, 1276
 intratracheal treatment of, 650
 medical treatment of, 1343, 1412
 pulmonary, 446
 Turpentine in scarlet fever, 1480
 Tympanites, 793
 Typhoid, oleum ricini in, 275
 Ulcers of cornea, 159
 treatment of, 716
 Urethritis, 504
 Vertigo, 1135
 Vomiting, cyclic, 1342
 White of egg lemonade, 1068

CURRENT MEDICAL LITERATURE

INDEX OF TITLES

Explanation: This index covers titles and subjects of original articles published in the leading medical journals of the world during the past six months. The titles, and the journals in which they appeared, were published weekly in the Current Medical Literature department, to which references are made. The figures in () refer to the paragraph; the number following, to the page in THE JOURNAL. For instance, "Abdomen, injuries of the, (94) 1547," refers to page 1547 of THE JOURNAL, on which is found opposite paragraph 94, the title of paper and name of author, viz., "Injuries of the Abdomen. Samuel L. Ensminger." This title is listed under the journal in which the article appeared: "Medical and Surgical Monitor, November 15." Titles of articles which appeared in THE JOURNAL are indicated by an asterisk (*) before the page number.

- Abdomen, injuries of the, (94) 1547
 inflamed, telephonic properties of, (68) 1615
 penetrating wounds of, (82) 1482
 Abdominal cases, clinical notes on, (14) 1615
 cases, some points in treatment of, post-operative, (27) 1414
 cases, statistical report of, (71) 1415
 cavity, foreign bodies accidentally left within the, (19) 1136
 cavity, sensibility in, (108) 339
 incision, resuturing the suppurating, (88) 861
 injury, treatment of, from horse's kick, (50) 339
 lesions, diagnosis in, (29) 447, (25) 506
 pain in typhoid fever, significance of, (56) 1345
 supporter, new, (48) 941
 surgery, (142) 1346
 surgical cases, some, (23) 283, (99) 653, (133) 653
 wall, anterior, clinical remarks on some tumors of, (17) 1011
 wounds, treatment of, (5) 1075
 Ablatio placentae, (71) 332
 Abney pellet test, modification of, for ready detection central scotomata, (58) 652
 Abolitionism, (29) 1144
 Abortion and miscarriage, (36) 46
 and premature labor, pathologic conditions causing, (35) 861
 and sterility, (48) 933
 cases of, (32) 1285
 criminal, prognosis and treatment of, (29) 454
 gynecologic and obstetric aspect of repeated, (15) 1615
 treatment of, (103) 1554
 Abortions, (74) 1482
 Abscess, bronchiectatic, of lung, (27) 794
 cerebellar, after infection through labyrinth, (97) 46
 double mastoid, three cases of simultaneous operation for, (102) 1137
 hepatic, case of, (28) 794
 in abdominal wall due to fish-bone perforating intestine, (51) 1621
 mammary, treatment of, by cold, (37) 940
 of fixation, puerperal infection treated by, (34) 1011
 of the lung following acute lobar pneumonia, *739
 pelvic, treatment of, (136) 1415
 prostatic, prerectal curvilinear incision for, (121) 1415
 subdiaphragmatic, of splenic origin, (79) 934
 subpectoral, (51) 718
 temporo-sphenoidal, (89) 104
 Abscesses, (77) 161
 adenomas, adipose tumors, etc., (71) 448
 in right iliac region, (49) 104
 Abscesses, lumbar spinal, treatment of, (89) 395
 Absinthe, new method of analysis of, (23) 454
 Absorption by peritoneum, (116) 339
 Abstinence from all food except water to reduce weight in diseases, (144) 220
 Academy of Medicine, the new, (23) 1647
 Accessory sinuses, diseases of, (95) 395, (103) 1137
 Accident insurance laws, physician and, (61) 941
 Accidental cures, (175) 653
 injuries, two hundred, (163) 1548
 Accidents, damages for, (66) 1144
 Accouchement forcé and surgical accouchement, (39) 226
 forcé, plea for more frequent use of, (147) 1138
 forcé with use of Bossi's dilator, (52) 868
 Acetanilid cyanosis, (42) 718
 Acetate of aluminum, local use of, (123) 1382
 Acetone, latest research on clinical significance of, (34) 590
 series of products in connection with diabetic coma, (10) 339, (4) 513
 Acetonemia, fatal, (80) 1137
 Acetonuria in gynecologic affection, (141) 727
 Acetozone in typhoid fever, (157) 448, (57) 1345
 Acid, a new paired, in ox gall, (106) 1554
 factors of gastric fluid, determination of, (5) 1345
 lactic, proof of, in gastric juice, (81) 1217
 tri-chloro-acetic, local action of, (89) 1415
 Acidophile bacteria, presence of, in feces, (76) 1422
 Acid-proof bacilli in pulmonary gangrene, (124) 395
 Acid-resisting group of bacteria, etiologic significance of, (94) 162
 Acids, action of, on voluntary muscles and blood vessels, (19) 1216
 organic action of certain, on intestines, (31) 868
 Acne, (176) 1416
 by exposure to x-rays, results obtained in treatment of, *313
 vulgaris, etiology and treatment of, (42) 1547
 vulgaris, viola tricolor in, (95) 514
 Aconite and digitalis, employment of, in cardiac disease, *764
 Acoustic tract, the, (93) 46
 Acquired characters, non-heredity of, (30) 277
 Acrodermatitis suppurativa, (128) 1012
 Acromegaly with cause and autopsy, (107) 1279
 Acroparesthesia, (24) 1136
 Acroparesthesias, traumatic, (63) 1216
 Actinic ray, treatment of diseases by the, (130) 1279
 rays, the, (22) 1345
 sunlight, concentrated, in tuberculosis, (18) 1278
 Actinomyces asteroides, life history of, (37) 454
 lesions produced by, (121) 170
 like development of some acid-resisting bacilli, (38) 454
 Actinomycosis, ano-rectal, (39) 726
 human, (91) 1422
 of chest organs, (56) 513
 of lower jaw, (49) 339
 Actinoscopy, determining outline of heart with, (66) 726
 Acute and chronic terms, significance of, (20) 1481
 general infections, local pathology of, arising through thyroid tissue of fauces, (16) 933
 Infectious diseases, our duty to public in, (101) 1279
 manifestations of chronic disease, (1) 1647
 Adams-Stokes disease, (93) 1622
 Addison's disease, case of, (118) 719
 disease, researches into cause of, (148) 862
 disease, with the aid of tuberculin in diagnosis, (77) 1137
 Address, Albany Medical College, (92) 1279
 Alumni Association of Medical-Chirurgical College, (124) 273
 American Association of Obstetricians and Gynecologists, (21) 1414, (129) 1415

 Medical Society of the County of Kings, (113) 219
 Medical Society of State of Missouri, (87) 1482
 Medical Society of the State of Pennsylvania, (17) 1004
 Medico-chirurgical Hospital of Philadelphia, (136) 47
 Melbourne Medical Association, (23) 1488
 New York State Medical Association, (94) 1415
 Address, North Carolina Medical Society, (177) 162, (160) 396
 Ohio Medical University, (68) 46, (104) 278
 Ohio Valley Medical Association, (54) 1070
 on behalf of alumni, (83) 652
 Ontario Medical Association, (99) 162, (67, 110) 219
 Pennsylvania State Medical Society, (64) 1279
 president's, (106) 719
 San Joaquin Valley Medical Society, (126) 1482
 section of Otolaryngology, (13) 726
 Southern California Medical Society, (126) 105
 State Society Iowa Medical Women, (69) 332
 Texas Medical Association, (108) 46
 Toledo Medical College, (120) 105
 Training School of Reading Hospital, (158) 653
 University of California, (112) 934
 University of Edinburgh, (13) 801
 Washington State Medical Society, (59) 933
 Wayne County Medical Society, (94) 1482
 Woman's Medical College, (125) 278
 Adenitis, transformation of, in animal organism, (111) 869
 Adenitis in infants and children, significance of, (176) 162
 tuberculous, (132) 105
 tuberculous cervical, surgical treatment of, (121) 448
 Adenocarcinoma, hepatic, (55) 46
 of male breast, (16) 1481
 successful removal of cecum and ascending colon in, (39) 447
 Adenoid operation, choice of anesthetic in, (16) 659
 tissues, chronic hypertrophy of, (7) 110
 Adenoids, (66) 104
 and hypertrophied faucial tonsils as portals of infection, (98) 1482
 and their complications, (64) 719
 adenoma, (100) 1000
 Adenoma of nose, (5) 394
 papillary, simultaneous occurrence of, in kidney and uterus, with metastases, (12) 1621
 Adhesions, post-operative, prevention of, (127) 653
 Adipose tumors, (77) 161
 Adiposid dolorosa, (33) 51, (65) 802
 Adnexa, origin of cysts of, (65) 802
 Adnexal infection, limits of medical treatment of, (21) 589
 Adrenal chlorid in urethral work, (15) 1645
 ectopia of, (93) 448

- Adrenalin, (21) 401
and phototherapy, (34) 726
in general practice, usefulness of, (111) 278
in ophthalmology, use of, (87) 277
in rhino-laryngology, (83) 1075
in urinary disease, (87) 660
in urologic practice, (36) 861
treatment of uterine hemorrhage with, (95) 1210
- Adrenals, rupture of, (95) 219
- Adult knee, diagnosis and management of, some more common lesions of, (78) 104
- Aetios of Amida, A. D. 540, the obstetrics and gynecology of, (9) 1621
- Æstivo-autumnal fever in Manhattan Island, (2) 718
- African lethargy, condition of central nervous system in case of, (3) 1011
- Age, influence of, on surgical operations, (46) 447
of consent, (34) 718
- Agglutination, (29) 801
improvement in technic of, (68) 51
in mixed infection, (97) 660
mechanism of, (106) 660
of pneumococci and theory of agglutination, (100) 660
researches on, (105) 660
the part of the microbic envelopes in, (31) 801
- Agglutinins, study of, (51) 1482
- Agitation, causes and treatment of, (42) 1422
- Ague, environment as a cause of, (21) 801
treated by hypodermic injections of quinin, (7) 1488
- Agurin, a new diuretic, (144) 1070, (113) 1415
- Aims and means in medicine, (12) 659
- Air, carbonic oxid and carbonic acid in vitiated, (24) 1554
cushions, inflation of, (94) 802
entrance of, into the veins, (50) 718, (64) 1345
passages and gullet, upper, diagnosis and treatment of foreign bodies in, (3) 726
passages, foreign bodies in, (33) 1422
passages, upper, medicated steam in treatment of, (75) 1422
tract in children, early treatment and catarrhal conditions of upper, (67) 1210
- Albany hospital, aseptic technic in, (122) 220
- Albargin or gelatose silver in treatment of gonorrhea, (22) 1546
- Albinism, case of, (19) 940
- Albumin and sugar, (80) 795
and sugar, pocket apparatus for testing for, at bedside, (113) 284
bodies in exudates and urine precipitated by acetic acid, (91) 802
gastric digestion of, (53) 1352
metabolism, influence of lecithin on, (42) 1285
precipitins, (79) 1217
- Albuminoids, chemistry and biology of, (89) 402
in blood, simple method for quantitative determination of, (68) 1075

- coli, B. typhosus and related species, media for distinguishing, (6) 50
- coli communis and B. typhosus, comparative study of bacilli intermediate between, (122) 395
- diphtheria, persistence of varieties of, (115) 395
- megatherium, angina from, (48) 513

- Bacillus pestis*, contribution to study of, (11) 1011
proteus vulgaris in surgery, rôle of, (69½) 277
pseudo-tuberculosis rodentium, relation of *bacillus pestis* to, (11) 1011
pyocyaneus, biology of, (18) 111
pyocyaneus, waste products of, (71) 51
typhosus, ocular changes produced by, (135) 1138
Bacteria, acid-fast, (104) 284
 acid-resisting, (69) 226
 digestion of, (26) 1554
 flagellation of, (61) 454
 influence of discovery of relation of, to disease, (127) 448, (115) 1005, (93) 1279
 non-elimination of, through the kidneys injected into arterial circulation, (111) 454
 simple method of fixing, without drying, (50) 454
 that store nitrogen, and their significance in agriculture, (73) 941
 to disease on practice of medicine, influence of discovery of, (44) 794
 to disease, relation of, (124) 220
Bacterial filter, simple, for small quantities of fluid, (58) 941
 flora of intestinal mucosa of normal rabbit, study of, (7) 1004
 flora of nose and ear, (132) 340
 hemolysin and antihemolysin, (58) 111
 research, methods of, (73) 454
 virulence, essence of, (90) 339
 virulence in vitro, increase of, (2) 1216
Bactericidal immune sera, action of, (126) 339
Bacteriologic diagnosis, place of, in medicine, (4) 1011
 research, improved technic for, (54) 1554
Bangkok, climate and diseases of, (3) 940
Banti's disease, cases of, (1) 659
 disease, splenectomy and Talma operation in, (59) 401, (82) 1422
 disease, surgery and hepatic otopherapy in, (129) 340
Barbadoes, malarial and filarial disease in, (5) 50
Barber-surgeons, (33) 1414, (24) 1482
Barker method, modification of, for treatment of fractures of patella, (18) 1004
Barlow's disease, (65) 869
Bathing facilities in Sydvaranger district, (131) 514
 in Finland, arrangements for, (120) 514
Baths as source of infection, (95) 1217
 influence of, on gas exchange, (32) 111
Battle of the clubs in Germany, present status of, (121) 52
 "Baudelocque, Shueltze, Duncan methods," what do we understand by, (94) 869
Beatson's cure of mammary cancer, (33) 1004
Beaumont, Wm., *1223
Bed-sores, chemical means for prevention of, (114) 1210
Bee disease, microbe of, (37) 1216
Bence Jones albumin, observations on nature of, (59) 104
 albumose, rapid reaction of, (129) 1138
Benedict's disease, (42) 801
Berg's, J., surgical clinic, (8) 1414
Berl-berl at Diego Garcia, (9) 659
 committee, report of, (129) 514
 discussion on, (1) 940
 further experiments in connection with pathology of, (15) 454
 katjang idjo in, (11) 1647
 theory of causation of, by toxin conveyed by rice, (15) 513
Berlin Charity Hospital, feeding the sick at, (117) 802
 surgical observations in, (21) 219, (7) 277, (8) 394
Biblical-Talmudic pathology, (118) 869
Bichlorid of mercury, intravenous injections of, (62) 507
Bifocal lenses, (25) 283
Bile, chemical nature of, after cholecystotomy, (123) 395
Bilharzia hematobia in Cyprus, (10) 1011
 lectures on, (19) 51, (22) 169, (21) 225, (13) 339
Biliary acids, influence of, on surface tension, *630
 obstruction, some recent surgery for, (58) 1279
 passages and gall bladder, medical treatment of, (111) 1547
 passages, surgery of, (46) 1011
 system, illustrative errors and difficulties in diagnosis of affection of, (29) 277
Binoocular magnifier for use in operating, *1323
Biogenesis and heredity, (19) 1414
Biologic blood test, practical results of, (56) 1011
 properties of milk, are they concerned in nutrition, (12) 794
Biology to medicine, relation of, (6) 110
Bismuthose, favorable report on, (65) 726
Blackwater fever, (72) 513
 fever from Philippines, case of, (6) 794
 fever, nephrotomy in anuria of, (44) 1285
Bladder affections and myomata, relation between, (89) 1217
 cases, some obstinate, (76) 219
 drainage, advantages of, (44) 1278
 entire cataract slipped from physician's hand into, (39) 1011
 fatty degeneration of, as factor in pathology of genito-urinary disease, (57) 1070
 in male, chronic diseases of, (86) 162
 mole, anatomy and etiology of, (68) 1012
 mucosa, power of absorption and elimination of, (88) 1422
 rupture of, (62) 402
 suture of, after sectio alta, (66) 1422
 technic of Maydl's operation for exstrophy of, (44) 1488
 tumors, inclusions in, (89) 1622
 ulcer of, *124
 urine separator, (71) 169
Blastomycetes, tumor-like lesion in lung of horse caused by, (112) 395
Blastomycosis, cutaneous, (26) 225
 of skin, case of, (17) 1209
Blennorrhea of lachrymal sac caused by presence of rhinolith, (53) 1005
Blind, improved writing and reading apparatus for the, (37) 1422
Blister test, negative results of, (115) 941
Blood, bacteriologic study of, in surgical suppurations, (65) 402
 bacteriology of the, (27) 1488
 chemical composition of chloretic, (92) 1622
 cleansing function of kidneys, (85) 339
 coagulation of, (125) 170
 corpuscles, mode of action of various laking agents on, (126) 395
 count, approximate, from dried specimens, (48) 590
 count in pregnancy and parturition, (88) 513
 counts in abdominal diseases, value of, (9) 1421
 examination as aid in diagnosis, (28) 1488
 examination from standpoint of general practitioner, (78) 448
 examination in severe burns of skin, (15) 1278
 in certain cutaneous nervous diseases, (76) 277
 in disease, alkali tension of, (68) 111
 in disease, the, (30) 283
 in relation to anesthesia, (74) 719
 in its relation to surgical diagnosis, (69) 1070
 in urine, significance of, (148) 653
 influence of leucocytic serums on morphology of, (77) 284
Blood, influence of local hypotherapeutic measures on composition of, (129) 802
 influence of toxins of diphtheria and tetanus on elements of, (134) 727
 internal friction of, (68) 513
 letting, (114) 219
 new procedures for examination of, (14) 225
cold-blooded animals, interaction of, (50) 1482
 of pregnancy and puerperium, (75) 1415
 physiochemical researches on normal, (134) 340
 plasma, hemolytic, (80) 1217
 poisoning, bacteriologic examination of blood in respect to prognosis of, (61) 1353
 pressure, determination of, (130) 455
 pressure in mental disease, observations of, (16) 225
 pressure, measurement of, in man, (84) 941
 pressure, technic of measuring, (43) 1352
 quantitative changes in, in pulmonary tuberculosis, (27) 332
 reagent, a new, and its sensibility for crystallographic blood demonstrations, (96) 1217
 sera, antihemolytic action of, (53) 1554
 sera, milk and cholesterol, antihemolytic action of, (55) 1482
 serum and plasma, bactericidal action of, (125) 284
 serum, influence of spleen on natural or acquired hemolytic properties of, (117) 395
 serum, nature of, (30) 1647
 test, biologic, (101, 102) 51
 test, history of biologic, (103) 284
 value of examination of, to general practitioner, (40) 1209
 variations of alkalinity of, (46) 1352
 vomiting, diagnostic and prognostic signification of, (76) 1488
Blushing, morbid dread of, (71) 660
Body tracings, flexible curve for, (98) 162
Boils, treatment of, (34) 513
Böckellus' work on plague, (96) 1075
Bone bobbin, new, for uniting divided intestine, (7) 659
 formation, heteroplastic, (39) 401
 formation, traumatic intramuscular, (75) 339
 grafting, new method, (17) 219
Bones, experimental changes in, from infection, (81) 169
 of face and nose, deformities of, (106) 162
Books, sterilization of, (24) 940
Boric acid, recent research on effects of, as preservative, (119) 402
Borderland cases, advantages of early surgical intervention in, (110) 46
Boric acid in meats, assumed harmlessness of, (70) 1554
Boss's dilator, value of, (76) 51
 rapid dilator, (95) 454
Bothriocephalus latus, (78) 46, (92) 448
 latus, case of, (149) 934
 latus in the cat, (43) 1554
Botryomycosis, (72) 51
Bottini incisor, danger from manipulations of, (105) 454
 operation, (55) 1011
 operation, complete prostatectomy and the, (26) 1285
 operation, indications for, (37) 1488
 operation, limitations and indications for, (85) 333
 operation, permanent results, failures and relapses following, (3) 45
 operation, present status of, (78) 161
 operation, relief with, for retention of urine, (49) 395
 operation, statistics of, (92) 514
 operations, successful after long complete retention, (91) 514
Bottini, complete retention, (91) 514
Bottles that separate into halves, (105) 802
Botulism, the antitoxin curve in the immunization against, (16) 111
Bowel, acute obstruction of, (58) 161, (84) 219
 obstruction from Meckel's diverticulum, (70) 1615
 perforation of, in typhoid fever, (125) 1415
Bowels, obstruction of, (116) 1210
 obstruction of, from Meckel's diverticulum, *810
Boys and girls, to what extent should physician supervise education of our, (127) 1005, (112) 1279
Brachydaetyl, (111) 1144
Brachial plexus, avulsion of, (65) 861
Brain, concussion of the, (155) 1138
 function, cerebral localization and, (5) 45
 injury, report of cases of, (84) 934
 injury, severe, without focal symptoms, *1458
 misleading gunshot wound of, (42) 506
 surgery, present status of, (39) 1004
 syphilis, clinical types of, (23) 46
 syphilis, surgery of, (67) 1353
 tetanus poison neutralizing property of, (107) 660
 treatment of wounds of, (84) 169
 tumors and abscesses, six cases of, (75) 1488
 tumors, brief resume of, (57) 1415
 tumors, surgery of, from neurologist's standpoint, (1) 1546
 tumors, symptoms and diagnosis of, (112) 402
Branham, J. H., (137) 1415
Bread in therapeutics, (117) 227
Breast, esthetic ablation of tumors of, (35) 1285
 excision of, (133) 1138
 hysterical hemiplegia and hysterical, (166) 934
 nursing, study of, (42) 660
Breath, offensive, causes and treatment of, (145) 633

 Incontinence of urine in children, electrical treatment of, (26) 1144
 of urine in female, (69) 861
 Index of diseases alphabetically arranged, (95) 861, (107) 1482
 the cephalic, (92) 1012
 India, medical evidence in, (21) 339
 surgical observations in, (69) 1482
 Indiana, mineral springs of, (136) 862
 Indian in urine, technic of colorimetric determination of, (57) 1075
 Indicanuria, (69) 1422
 Indol and skatol, (26) 283
 Industrial legislation and otology, (66) 660
 Inebriates, necessity of legal adjudication and restraint of, (143) 1070
 Inebriety, (156) 396, (143) 1070
 periodicity of, (80) 1482
 public care and treatment of, (62) 1137, (115) 1482
 some early stages of diseases of, (4) 1209
 studies on etiology, (108) 1210
 Infancy and childhood, pathologic specimens in various diseases of, (45) 1005
 Infant feeding, (179) 162, (53) 277, (57) 402, (103) 795, (160) 934, (20) 1546, (22½) 1615
 feeding, Backhaus' milk in, (36) 660
 feeding, measurement of amount of food in, (40) 660
 feeding, "Nahrzucker" in, (60) 513
 feeding, substitute, (63) 507
 mortality, (7) 589
 Infantile disturbances, (51) 1069
 lues, study of consequences of, (79) 226
 mortality, (100) 653, (49½) 1345
 paralysis, subcutaneous division of tendo achillis for relief of equinus following, (25) 277
 Infantilis, degenerative, complicated with pubertal dys-thyroidia, (36) 801
 and senilism, (3) 1332
 rectal prolapse in, (57) 1488
 Infection, pathology of, (27) 1332
 types of, produced in man by intermediate members of the typhoid colon group, (20) 1069
 Infections, acute general, originating in lymphoid tissue, (13) 1645
 Infectious diseases, facts concerning certain common, (148) 934
 diseases, organic exchanges in, and during convalescence of, (33) 868
 diseases, review of some interesting work on, (47) 161
 diseases, what precautions should be taken to prevent spread of, (150) 162
 processes of adenoid structure in children, constitutional manifestations due to, (132) 1070
 suppurative processes in peritoneal cavity, treatment of, (41) 332
 Inflammations of appendix, (70) 1279
 Influenza, (29) 1488
 bacillus, new bacillus of group of, (109) 660
 bacillus, resistance of, (58) 454
 bacillus, studies in biology of, (25) 1554
 Influenza, cause of heart irregularity in, (6) 1332
 epidemic considered in relation to quarantine against tuberculosis, (56) 447
 gastrointestinal, (10) 110
 in children, (174) 653
 Infrapubic section for prostatectomy, *955
 Inginal bandage, new, *1459
 Inhalations, medicated, (35) 1144
 Inhaler, improved aseptic etherizing, *1185
 new, for operations on eye and face, (20) 219
 Injection, rectal electric, (46) 1144
 Injections, soluble mercurial, in large doses, advantages of, (49) 513
 Inoculation, successful protective, of cattle against anthrax, (81) 340
 Insane, cases of peculiar motor manifestations of, (52) 1345
 hospital treatment of, as carried out at London County Asylum, (5) 1216
 in Minnesota, care of, (50) 1547
 in New York state, (113) 1005
 in North America, review of history of, (45) 506
 kidney diseases of, (125) 47
 on state care and supervision of, (8) 586
 recent progress in the housing of the, (3) 1216
 treatment of, in private practice, (8) 1209
 Insanity, (124) 333
 a rare case of, *1256
 acute confusional, pathogenesis and pathologic anatomy of, (115) 660
 acute, from dental irritation and toxemia, (102) 162
 causes and remedies of, (133) 1547
 crime in, (19) 339
 criminal equivalent of, (14) 1069
 criteria of, (63) 652
 feigning of, by traumatic lunatic for personal damage reasons, (48) 332
 hebephrenic, (50) 332
 hydiatic procedures in, (68) 652
 initial symptoms of, and its physical basis, (122) 333
 post-operative, (91) 941
 relation of neurasthenia to, (6) 1216
 secondary traumatic, (85) 1346
 some curable forms of, (82) 1005
 Insomnia, (73) 1137, (146) 1416
 treatment of, of pulmonary tuberculosis, (70) 1070
 Insufficiencia pylori as sequela of chronic gastritis, (32) 1004
 Inter-ilio-abdominal disarticulation, (40) 940
 Intermittent fevers, remarks concerning, (13, 26) 1011
 Internal capsule, are clinical localizations possible in, (75) 169
 medicine, study of, (37) 1209, (60) 1415
 organs, injuries of, (124) 1210
 International Conference for Prophylaxis of Syphilis and Venereal Diseases, review of second, (22) 1554
 Conference of Tuberculosis, scientific work of, (40) 1488
 Congress of Gynecology and Obstetrics, Rome, transactions of, (50) 1144
 Congress of Gynecology at Rome, (67) 1488
 Congresses of Gynecology and of Naturalists, reports of, (65) 1621
 Red Cross, seventh conference of, (8) 506

 hypertrophy of, (58) 1285
 hypertrophy of, cured by resection of vas deferens, (74) 1422
 massage of, (86) 284
 pancreas and diaphragm, surgery of, (33) 1069, (36) 1137, (33) 1209, (38) 1278, (39) 1345, (41) 1415, (36) 1482, (36) 1547, (38) 1615
 the, from the general practitioner's standpoint, (45) 1069
 total extirpation of, for radical cure of enlargement of that organ, (1) 401
 treatment of, hypertrophy of, by denudation, (74) 284
 use of cautery on, (42) 46
 Prostatectomy, (155) 1416
 cases of, (29) 652
 complete, and Bottini operation, (26) 1285
 perineal, (36) 284, (107) 333, (4) 1421
 suprapubic, (84) 333
 technic of, (120) 1415
 Prostatic disease, treatment of, by hot solutions, (103) 219
 fibers, chronic contraction of, encircling vesical neck, (28) 860
 obstruction, surgery of, (60) 1547
 Prostatic surgery, reasons why perineal route is preferable to suprapubic route in, (67) 861
 surgery, recent progress in, (10) 277
 Prostatitis, (100) 1488
 Prostatitis, (142) 1070
 chronic, (124) 727, (118) 1346
 gonorrheal, acute and chronic, (114) 1005
 reaction of prostatic secretion in chronic, (107) 226, (91) 660, (88) 941
 treatment of parenchymatous, (94) 1005
 Protargol, use of, in blennorrhea neonatorum, (107) 52
 Protargon, differential value of, in exploratory puncture of thorax, (63) 226
 Proteid substances, electrolysis of, (119) 170
 Proteus infection and hospital gangrene, identity of, (127) 1415
 Prurigo, Hebra's, (35) 726
 lymphatica, (38) 1621
 Pruritus ani, *74
 cutaneous, external treatment of, (115) 46
 Prussian Medical Chambers, transactions of, (71) 1554
 Pseudo-arthritis, treatment of, by metallic "agrafage," (15) 1647
 Pseudo-cirrhosis of liver, pericarditic, (98) 1005
 Pseudoconitine and japaconitine, action of, (21) 1216
 Pseudo-bulbar paralysis, pathology of motor disturbances in, (111) 869
 Pseudo-cyesis, ovarian irritation as a factor in etiology of, (6) 161
 Pseudo-endometritis, pathologic anatomy of, (62) 284
 Pseudo-epilepsies, thyroid in, (120) 1070
 Pseudo-hypertrophy, paradoxical, following infantile cerebral hemiplegia, (50) 1345
 Pseudo-leukemia, splenic, case of, (104) 1210
 Pseudo-meningitis, psychogenic, (106) 402
 (68) 332
 (97) 1415
 6) 1075
 Pseudo-strangulation, internal, of neuropathic origin, (20) 1647
 Psoriasis, discussion on treatment of, (12) 1285
 sepsis, (62) 51
 Psychiatry, outlines of, in clinical lectures, (85) 719
 practical suggestions which, can give to pedagogy, (82) 1012
 study of, (39) 861
 Psychic therapeutics, is it wise for regularly practicing physician to spend time in investigating, (3) 933
 Psychological medicine, suggestive therapeutics or, (37) 219
 Psychology as applied to modern medicine, (50) 395
 to medicine, relation of, (144) 162
 Psychopathies, classification of, (79) 1012
 Psychoses, alcoholic, (59) 161
 alcoholic, in women, (110) 333
 of early puberty, (11) 718
 Pterygia, nature and treatment of, *296
 Pterygium, modern treatment of, (18) 394
 Ptomain of milk, wholesale poisoning from the, (51) 933
 Ptos of traumatic origin, its significance and prognosis, (38) 1075
 Puberty and genius, (82) 719
 Public health, pioneers of, (18) 51
 health, possibilities of future legislation in matters of, (9) 1488
 schools, medical examination in our, (106) 653, (86) 934
 Puerperal convulsions, cases of, (110) 719
 fever, annual variation of, (7) 50
 fever, forensic importance of, (63) 1144

 operation for, with unusual termination, (129) 1210
 surgery of, (38) 940
- Varicose ulcers, treatment of, (121) 284
- veins of lower limbs, (12) 1553
- veins, operative treatment of, (15) 933
- Variola and varicella, differential diagnosis between, (10) 225
 cultivation of virus of, (89) 1488
 prophylaxis of, (100) 1547
 researches on contagion of, (73) 1488
 sporozoan of, (22) 660
- Vas deferens, new method of suture of, (76) 1285
- Vasomotor ataxia, contribution to subject of, (1) 1345
- Vasogen salve, mercurial, (82) 1144
- Vegetarianism, (86) 226
- Veneral disease, Belgian circular warning against, (75) 941
 disease, prophylaxis of, (20) 933, (95) 941, (63) 1554
 diseases, educational limitations of, (34) 1345
 diseases in Christiana in 1901, (94) 1488
 diseases, out-treatment of women with, (124) 514
- Venesection, *1237
 in art and practice, (36) 513
- Venoms, (22) 454
- Venous system of temporal bone and its relations to complication of mastoid disease, (17) 586
- Ventrofixation and ventrosuspension of uterus, are they justifiable, (79) 1415
 value and results of, (115) 934
- Ventroscopy as examination method in vaginal cellotomy, (42) 1488
 by the vaginal route, (103) 454
- Verbal amnesia, remarks on, (15) 1481
- Verbal obsessions, (9) 513
- Vermiform appendix as cause of intestinal obstruction, (108) 653
 appendix, containing fecal concretion on black pin, (17) 225
 appendix, foreign bodies in, (30) 1414
 appendix, inflammation of, (8) 169
 appendix, inflammatory conditions of, (118) 795, (128) 1005
 appendix, when is it advisable to remove, when abdomen is opened for other reasons, *1019
- Vermin in bladder, (66) 46
- Vermont observation law for criminal insane, medicolegal phases of, (69) 652, (98) 653
- Versio-flexions, uterine, significance, pathogenesis and therapy of, (62) 1210
- Vertigo in neurological diagnosis, (4) 1278
- ocular, (5) 1278
- Vesical tone, relation of mentus urinarius to, (27) 46
- Vesicular mole, or fatty and cystic degeneration of the product of conception, (139) 1070
- Vessel phenomena, the, in aortic regurgitation and aneurism, (87) 1070
- Vibration massage in expulsion of kidney stones, (72) 1488
- Vienna Allgemeine Krankenhaus, teaching and practice of surgery in, (34) 1137
- Vioform in tubercular joints, (89) 1070
- Virchow, (82) 1279, (139) 1346, (31) 1621
 as a pathologist, (33) 860
 as a public man, (34) 860
 Nekrologos on, (104) 1415
 Prof. Rudolph, (119½) 1415
- Virchow's accident and illness, (30) 1621
- Viscera, abdominal, traumatic rupture of, without external signs of injury, *1032
 complete transposition of, (85) 104
 congenital and acquired transposition of, clinical observations on, (68) 1345
 solid, suture of, (25) 652
 thoracic and abdominal, demonstration of model of, (34) 506
 traumatic rupture of abdominal without external signs of injury, *1091
- Vision, color, sense, and hearing, examination of Victoria railway employees in, (24) 1488
 defects of, or of hearing in relation to development of children, (113) 861
 models for demonstrating elementary physiology of, (29) 1482
 monocular, (129) 448
 some neglected points in physiology of, (35) 1645
- Visir-meter, (40) 1285
- Visual apparatus, symmetry of our, as dual organ, *612
 impulse, origin of a, (16) 868
- Vital statistics and sanitary reform, (8) 110
- Vitreous chamber, foreign body in, *987
 remarkable vascular growth into the, (56) 652
- Vivisection, (32) 277
 abuse of, (55) 1210
- Volunteer regimental medical officer, position of the, (8) 1075
- Volvulus as cause of intestinal obstruction, (19) 1615
 case of, with torsion of entire mesentery, (61) 1137
 of sigmoid flexure, diagnosis of, (109) 340
- Vomit by nasal affections, exaggeration of reflex spasmodic effort to, (50) 726
- Vomiting in pregnancy, (186) 1416
 of pregnancy, pernicious, (42) 219
 pernicious, of pregnancy, (112) 1415
 recurrent, (3) 506
 recurrent, in children, (64) 1482
- Vulva, ulcerative lesions of, (66) 161
- War, my experience in, (151) 448
 wounds, modern, (82) 219
- Ward clinic, the, (8) 1004
- Wassmuth's inhaler, tests of, (103) 170
- Water cures, physicians and charlatans, (72) 660
 note on administration of, in disease, (6) 447
 potable, and how to procure it, (135) 47
 supply, municipal, methods and courses to be considered in adoption of, (20) 1209
 supply, present, and how to improve it, (134) 47
 supply, typhoid fever and, in Chicago, *1561
 therapeutic uses of, (114) 278
 supplies, municipal, (12) 652
- Weaning of puppies and new medical suggestion, (39) 339
- Webster-Baldy operation for retro-displacement of uterus, (43) 1278, (133) 1346
- Welger's stain, new observations on, (112) 52
- Weight deformities, study of mechanism of, (69) 340
- Well's disease, Widal reaction in, (114) 284
- West Africa, sanitary work in, (5) 940
- What to be and what not to be, (121) 105
- White blood corpuscles, pathologic relations of, (1) 1004
 Haven Sanatorium of free hospital for poor consumptives, year's work at, (14) 1345
 of egg, subcutaneous injections of, (30) 1345
- Why patients sometimes get worse, (162) 934
- Widal reaction in infancy and early childhood, (51) 1209
 reaction in typhoid, (107) 941
 reaction, results of examination of blood for, (9) 1209
 reaction, the, (21) 283
- Willan, Robert, and dermatology, (82) 934
- Wolff's transformation position, (129) 285
- Womanhood, how to assist young girls to, (53) 1069, (99) 1137, (110, 118) 1279
- Women nurses, trained, lessons drawn from practical experiences with, in military service, (77) 1615
 practitioners of Colorado, history of, (41) 46
 some etiologic factors in diseases of, (5) 447
- Wood's Hole, my summer in, (21) 506
- Woody phlegmon of neck, (123) 284
- Working capacity, impaired, (62) 941
- Wounds, abdominal, two laparotomies and the Mikulicz drainage in, (93) 1422
 and their treatment in the South African campaign, (79) 333
 in naval actions, treatment of, (1) 1075
 infected, (79) 1005
 infection of, from standpoint of insurance against accidents, (136) 396
 treatment of, (138) 105
 treatment of accidental, (85) 1075
 with discussion on what constitutes rational treatment, (8) 933
- Wry-neck, spasmodic, contribution to treatment of, (11) 1069
- Xeroderma pigmentosum, tumors of, (14) 1285
 pigmentosum, ocular alterations in, (31) 726
- X-ray apparatus and x-ray methods, (46) 1415
 and x-ray therapeutics, (65) 1615
 as a therapeutic agent, (149) 1138, (58) 1210, (167) 1416
 death due to, *1321
 dermatosis, case of, (16) 447
 in therapeutics, (38) 1482
 lesion treated by excision and skin graft, (108) 333
 some of the therapeutic uses of, (22) 394
 some uses of, other than diagnostic, (151) 719
 the, (4½) 1209
 therapeutic use of, (100) 507
 therapy and epithelioma, (11) 1645
 tube shield and specula for rectal cancers, (12) 1645
 variety in skin lesions treated by, (12) 447
- X-rays in cancer, (21) 1278
 in cancer, lupus, and Hodgkin's disease, (152) 719
 in surgery, (46) 1278
 in treatment of malignant growth, (9) 652
 some results that are being attained by use of, (150) 719
 therapeutic value of, (129) 934
 therapeutics of, (47) 1278
 use of, (139) 1483
- Yale to medicine, relation of, (11) 45
- Yeast, comparative tests of commercial preparations of, (67) 941
 fungus, new pathogenic, (62) 454
 in therapeutics, (89) 660
 ment extracts and preparations of, (130) 802
 sterile, for vaginal use, (57) 726
- Yellow fever, (32) 587
 fever and mosquitoes, comments on, (172) 1416
 fever, are vessels infected with, (27) 1615
 fever, attempt at physiologic treatment of, (133) 514
 fever, discussion on, (8) 940
 fever in etiology of progressive paralysis, (76) 111
 fever in Havana, on eradication of, (3) 1209
 fever, is mosquito factor in disseminating, (122) 278
 fever, mosquitoes and, (132) 514
 fever, new studies in, (135) 514
 fever on U. S. Ship Plymouth, in 1878 and 1879, (24) 1004
 fever quarantine, (141) 862
 fever, results in Havana in 1901, of disinfection of, (22) 801
 fever, treatment of, *117, (33) 933
- Yohimbin, (97) 111, (47) 941, (27) 1615, (55) 1621
 in infants, (11) 401
- Young girls, how to assist to womanhood, (99) 1137
- Zinc superoxide, (54) 277
- Zona, ophthalmic, value of dionin in, (39) 513
- Zones and centers, new scheme of, of human cerebrum, *828
- Zoster, further observations regarding malarial origin of, (21) 394
 glossitis, (58) 1070
 local, followed by general herpetic eruption, (115) 1547
- Zupplinger's scoliosis theory, (94) 660
- Zygomatico maxillary suture, (94) 727

CURRENT MEDICAL LITERATURE

INDEX OF AUTHORS

This Index includes the names of authors of articles which have appeared in this journal, as well as of those listed under Current Medical Literature. This practically includes the names of those who have published articles in the leading journals of the world. The * preceding the page reference indicates that the article appeared in full in THE JOURNAL.
